Part I
Getting started

1 History

This package began life as a LaTeX interface to select system-installed macOS fonts in Jonathan Kew’s \TeX, the first widely-used Unicode extension to \TeX. Over time, \TeX was extended to support Open Type fonts and then was ported into a cross-platform program to run also on Windows and Linux.

More recently, Lua\TeX is fast becoming the \TeX engine of the day; it supports Unicode encodings and OpenType fonts and opens up the internals of \TeX via the Lua programming language. Hans Hagen’s Con\TeXt Mk. IV is a re-write of his powerful typesetting system, taking full advantage of Lua\TeX’s features including font support; a kernel of his work in this area has been extracted to be useful for other \TeX macro systems as well, and this has enabled fontspec to be adapted for \TeX when run with the Lua\TeX engine.

2 Introduction

The fontspec package allows users of either \TeX or Lua\TeX to load OpenType fonts in a \TeX document. No font installation is necessary, and font features can be selected and used as desired throughout the document.

Without fontspec, it is necessary to write cumbersome font definition files for \TeX, since \TeX’s font selection scheme (known as the ‘NFSS’) has a lot going on behind the scenes to allow easy commands like \textbf{emph} or \textbf{bfseries}. With an uncountable number of fonts now available for use, however, it becomes less desirable to have to write these font definition (.fd) files for every font one wishes to use.

Because fontspec is designed to work in a variety of modes, this user documentation is split into separate sections that are designed to be relatively independent. Nonetheless, the basic functionality all behaves in the same way, so previous users of fontspec under \TeX should have little or no difficulty switching over to Lua\TeX.

This manual can get rather in-depth, as there are a lot of details to cover. See the document fontspec-example.tex for a complete minimal example to get started quickly.

2.1 Acknowledgements

This package could not have been possible without the early and continued support the author of \TeX, Jonathan Kew. When I started this package, he steered me many times in the right direction.

I’ve had great feedback over the years on feature requests, documentation queries, bug reports, font suggestions, and so on from lots of people all around the world. Many thanks to you all.

Thanks to David Perry and Markus Böhning for numerous documentation improvements and David Perry again for contributing the text for one of the sections of this manual.

Special thanks to Khaled Hosny, who was the driving force behind the support for Lua\TeX, ultimately leading to version 2.0 of the package.
3 Package loading and options

For basic use, no package options are required:

\usepackage{fontspec}

Package options will be introduced below; some preliminary details are discussed first.

3.1 Font encodings

The 2016 release of fontspec initiated some changes for font encodings and the loading of xunicode. The 2017 release rolls out those changes as default.

The now-default tuenc package option switches the NFSS font encoding to TU. TU is a new Unicode font encoding, intended for both \TeX\ and \LaTeX\ engines, and automatically contains support for symbols covered by \TeX\’s traditional T1 and TS1 font encodings (for example, \%, \textbullet, "u, and so on). As a result, with this package option, Ross Moore’s xunicode package is not loaded. Some new, experimental, features are now provided to customise some encoding details; see Part V on page 53 for further details.

Pre-2017 behaviour can be achieved with the euenc package option. This selects the EU1 or EU2 encoding (\TeX\ or \LaTeX, resp.) and loads the xunicode package. Package authors and users who have referred explicitly to the encoding names EU1 or EU2 should update their code or documents. (See internal variable names described in Section 5 on page 68 for how to do this properly.)

3.2 Maths fonts adjustments

By default, fontspec adjusts \TeX\’s default maths setup in order to maintain the correct Computer Modern symbols when the roman font changes. However, it will attempt to avoid doing this if another maths font package is loaded (such as mathpazo or the unicode-math package).

If you find that fontspec is incorrectly changing the maths font when it shouldn’t be, apply the no-math package option to manually suppress its behaviour here.

3.3 Configuration

If you wish to customise any part of the fontspec interface, this should be done by creating your own fontspec.cfg file, which will be automatically loaded if it is found by \TeX\ or \LaTeX. A fontspec.cfg file is distributed with fontspec with a small number of defaults set up within it.

To customise fontspec to your liking, use the standard .cfg file as a starting point or write your own from scratch, then either place it in the same folder as the main document for isolated cases, or in a location that \TeX\ or \LaTeX\ searches by default; e.g. in Mac\TeX: ~\Library/texmf/tex/latex/.

The package option no-config will suppress the loading of the fontspec.cfg file under all circumstances.
3.4 Warnings

This package can give some warnings that can be harmless if you know what you’re doing. Use the \quiet package option to write these warnings to the transcript (.log) file instead.

Use the \silent package option to completely suppress these warnings if you don’t even want the .log file cluttered up.

4 Interaction with \LaTeX{} 2ε and other packages

This section documents some areas of adjustment that fontspec makes to improve default behaviour with \LaTeX{} 2ε and third-party packages.

4.1 Verbatim

Many verbatim mechanisms assume the existence of a 'visible space' character that exists in the ascii space slot of the typewriter font. This character is known in Unicode as U+2423: BOX OPEN, which looks like this: ‘ ’.

When a Unicode typewriter font is used, \LaTeX{} no longer prints visible spaces for the verbatim* environment and \verb* command. This problem is fixed by using the correct Unicode glyph, and the following packages are patched to do the same: listings, fancyvrb, moreverb, and verbatim.

In the case that the typewriter font does not contain ‘ ’, the Latin Modern Mono font is used as a fallback.

In 2019, \LaTeX{} will use a new command \verbvisiblespace for internal commands and for third party packages. If this new command is defined, fontspec’s patching code here will be entirely disabled and the packages listed above should no longer rely on fontspec to redefine their internals.

4.2 Commands for old-style and lining numbers

\oldstylenums \LaTeX{}‘s definition of \oldstylenums relies on strange font encodings. We provide a fontspec-compatible alternative and while we’re at it also throw in the reverse option as well. Use \oldstylenums{⟨text⟩} to explicitly use old-style (or lowercase) numbers in ⟨text⟩, and the reverse for \liningnums{⟨text⟩}.

4.3 Italic small caps

\itshape Note that this package redefines the \itshape, \slshape, and \scshape commands in order to allow them to select italic small caps in conjunction. With these changes, writing \itshape\scshape will lead to italic small caps, and \upshape subsequently then moves back to small caps only. \upshape again returns from small caps to upright regular. (And similarly for for \slshape. In addition, once italic small caps are selected then \slshape will switch to slanted small caps, and vice versa.)
4.4 Emphasis and nested emphasis

\texttt{\textbackslash em\textbackslash em} allows you to specify the behaviour of \texttt{\textbackslash emph} nested within \texttt{\textbackslash emph} by setting the \texttt{\textbackslash em\textbackslash in\textbackslash nershape} command. For example,

\texttt{\renewcommand\em\textbackslash in\textbackslash nershape{\upshape\scshape}}

will produce small caps within \texttt{\textbackslash emph{\textbackslash emph{...})}. The \texttt{\fontspec} package takes this idea one step further to allow arbitrary font shape changes and arbitrary levels of nesting within emphasis. This is performed using the \texttt{\em\textbackslash font\textbackslash declare} command, which takes a comma-separated list of font switches corresponding to increasing levels of emphasis. An example:

1. \texttt{\em\textbackslash font\textbackslash declare{\itshape,\upshape\scshape,\itshape}} will lead to ‘italics’, ‘small caps’, then ‘italic small caps’ as the level of emphasis increases, as long as italic small caps are defined for the font. Note that \texttt{\upshape} is required because the font changes are cascading.

The implementation of this feature tries to be ‘smart’ and guess what level of emphasis to use in the case of manual font changing. This is reliable only if you use shape-changing commands in \texttt{\em\textbackslash font\textbackslash declare}. For example:

\texttt{\em\textbackslash font\textbackslash declare{\itshape,\upshape\scshape,\itshape}}

\texttt{...}

\texttt{\scshape small caps \textbackslash emph{hello}}

Here, the emphasised text ‘hello’ will be printed in italic small caps since \texttt{\textbackslash emph} can detect that the current font shape is already in the second ‘mode’ of emphasis.

\texttt{\em\textbackslash reset} (by default just \texttt{\upshape}) and start again from the beginning.

4.5 Strong emphasis

The \texttt{\textbackslash strong} macro is used analogously to \texttt{\textbackslash emph} but produces variations in weight. If you need it in environment form, use \texttt{\begin{strongenv}...\end{strongenv}}.

As with emphasis, this font-switching command is intended to move through a range of font weights. For example, if the fonts are set up correctly it allows usage such as \texttt{\textbackslash strong{...\textbackslash strong{...}}} in which each nested \texttt{\strong} macro increases the weight of the font.

Currently this feature set is somewhat experimental and there is no syntactic sugar to easily define a range of font weights using \texttt{\fontspec} commands. Use, say, the following to define first bold and then black (k) font faces for \texttt{\strong}:

\texttt{\strong\textbackslash font\textbackslash declare{\bfseries,\fontseries{k}\selectfont}}

If too many levels of \texttt{\strong} are reached, \texttt{\strong\textbackslash reset} is inserted. By default this is a no-op and the font will simply remain the same. Use \texttt{\renewcommand\strong\textbackslash reset{\mdseries}} to start again from the beginning if desired.

An example for setting up a font family for use with \texttt{\strong} is discussed in \texttt{\textbackslash 4.3.1 on page 18}. 

8
Part II

General font selection

1 Main commands

This section concerns the variety of commands that can be used to select fonts.

\setmainfont{⟨font⟩}{⟨font features⟩}
\setsansfont{⟨font⟩}{⟨font features⟩}
\setmonofont{⟨font⟩}{⟨font features⟩}

These are the main font-selecting commands of this package which select the standard fonts used in a document, as shown in Example 1. Here, the scales of the fonts have been chosen to equalise their lowercase letter heights. The Scale font feature will be discussed further in Section 6 on page 26, including methods for automatic scaling. Note that further options may need to be added to select appropriate bold/italic fonts, but this shows the main idea.

Note that while these commands all look and behave largely identically, the default setup for font loading automatically adds the Ligatures=TeX feature for the \setmainfont and \setsansfont commands. These defaults (and further customisations possible) are discussed in Section 1 on page 21.

\newfontfamily⟨cmd⟩{⟨font⟩}{⟨font features⟩}
\setfontfamily⟨cmd⟩{⟨font⟩}{⟨font features⟩}
\renewfontfamily⟨cmd⟩{⟨font⟩}{⟨font features⟩}
\providefontfamily⟨cmd⟩{⟨font⟩}{⟨font features⟩}

These commands define new font family commands (like \rmfamily). The new command checks if ⟨cmd⟩ has been defined, and issues an error if so. The renew command checks if ⟨cmd⟩ has been defined, and issues an error if not. The provide command checks if ⟨cmd⟩ has been defined, and silently aborts if so. The set command never checks; use at your own risk.

\fontspec{⟨font⟩}{⟨font features⟩}

The plain \fontspec command is not generally recommended for document use. It is an ad hoc commands best suited for testing and loading fonts on a one-off basis.

All of the commands listed above accept comma-separated ⟨font feature⟩ = ⟨option⟩ lists; these are described later:

- For general font features, see Section 6 on page 26
- For OpenType fonts, see Part IV on page 33
- For \LaTeX-only general font features, see Part VII on page 59
- For Lua\TeX-only general font features, see Part VI on page 57
- For features for \AA\T fonts in \LaTeX, see Section 3 on page 60
Example 1: Loading the default, sans serif, and monospaced fonts.

\setmainfont{texgyrebonum-regular.otf}
\setsansfont{lmsans18-regular.otf}[Scale=MatchLowercase]
\setmonofont{Inconsolatazi4-Regular.otf}[Scale=MatchLowercase]

\rmfamily Pack my box with five dozen liquor jugs\par
\sffamily Pack my box with five dozen liquor jugs\par
\ttfamily Pack my box with five dozen liquor jugs

\setmainfont{Cambria}[ ... ]
in which the bold and italic fonts will be found automatically (if they exist) and are immediately accessible with the usual \textit and \textbf commands.

The 'font name' can be found in various ways, such as by looking in the name listed in an application like Font Book on Mac OS X. Alternatively, \TeXLive contains the otfinfo command line program, which can query this information; for example:

\texttt{otfinfo -i `kpsewhich lmroman18-regular.otf`}

results in a line that reads:

\begin{quote}
Preferred family: Latin Modern Roman
\end{quote}

(The ‘preferred family’ name is usually better than the ‘family’ name.)

\textbf{\textit{Lua\TeX} users only} In order to load fonts by their name rather than by their filename (e.g., ‘Latin Modern Roman’ instead of ‘ec-lmr10’), you may need to run the script luaotfload-tool, which is distributed with the luaotfload package. Note that if you do not execute this script beforehand, the first time you attempt to typeset the process will pause for (up to) several minutes. (But only the first time.) Please see the luaotfload documentation for more information.
2.2 By file name

Xe\TeX\ and \LaTeX{} also allow fonts to be loaded by file name instead of font name. When you have a very large collection of fonts, you will sometimes not wish to have them all installed in your system’s font directories. In this case, it is more convenient to load them from a different location on your disk. This technique is also necessary in Xe\TeX\ when loading OpenType fonts that are present within your \TeX{} distribution, such as /usr/local/texlive/2013/texmf-dist/fonts/opentype/public. Fonts in such locations are visible to Xe\TeX\ but cannot be loaded by font name, only file name; \LaTeX{} does not have this restriction.

When selecting fonts by file name, any font that can be found in the default search paths may be used directly (including in the current directory) without having to explicitly define the location of the font file on disk.

Fonts selected by filename must include bold and italic variants explicitly, unless a .\fontspec file is supplied for the font family (see Section 2.3). We’ll give some first examples specifying everything explicitly:

\begin{verbatim}
\setmainfont{texgyrepagella-regular.otf}[  BoldFont = texgyrepagella-bold.otf ,  ItalicFont = texgyrepagella-italic.otf ,  BoldItalicFont = texgyrepagella-bolditalic.otf ]
\end{verbatim}

\fontspec{} knows that the font is to be selected by file name by the presence of the `.otf` extension. An alternative is to specify the extension separately, as shown following:

\begin{verbatim}
\setmainfont{texgyrepagella-regular}[  Extension = .otf ,  BoldFont = texgyrepagella-bold ,  ... ]
\end{verbatim}

If desired, an abbreviation can be applied to the font names based on the mandatory ‘font name’ argument:

\begin{verbatim}
\setmainfont{texgyrepagella}[  Extension = .otf ,  UprightFont = *-regular ,  BoldFont = *-bold ,  ... ]
\end{verbatim}

In this case ‘texgyrepagella’ is no longer the name of an actual font, but is used to construct the font names for each shape; the * is replaced by ‘texgyrepagella’. Note in this case that UprightFont is required for constructing the font name of the normal font to use.

To load a font that is not in one of the default search paths, its location in the filesystem must be specified with the Path feature:

\begin{verbatim}
\setmainfont{texgyrepagella}[  Path = /Users/will/Fonts/ ,  UprightFont = *-regular ,  BoldFont = *-bold ,  ... ]
\end{verbatim}
Note that XeTeX and LuaTeX are able to load the font without giving an extension, but fontspec must know to search for the file; this can be indicated by using the Path feature without an argument:

\setmainfont{texgyrepagella-regular}[
  Path, BoldFont = texgyrepagella-bold,
  ...
]

My preference is to always be explicit and include the extension; this also allows fontspec to automatically identify that the font should be loaded by filename.

In previous versions of the package, the Path feature was also provided under the alias ExternalLocation, but this latter name is now deprecated and should not be used for new documents.

2.3 By custom file name using a .fontspec file

When fontspec is first asked to load a font, a font settings file is searched for with the name ‘⟨fontname⟩.fontspec’. If you want to disable this feature on a per-font basis, use the IgnoreFontspecFile font option.

The contents of this file can be used to specify font shapes and font features without having to have this information present within each document. Therefore, it can be more flexible than the alternatives listed above.

When searching for this .fontspec file, ⟨fontname⟩ is stripped of spaces and file extensions are omitted. For example, given \setmainfont{TeX Gyre Adventor}, the .fontspec file would be called TeXGyreAdventor.fontspec. If you wanted to transparently load options for \setmainfont{texgyreadventor-regular.otf}, the configuration file would be texgyreadventor-regular.fontspec.

N.B. that while spaces are stripped, the lettercase of the names should match.

This mechanism can be used to define custom names or aliases for your font collections. The syntax within this file follows from the \defaultfontfeatures, defined in more detail later but mirroring the standard fontspec font loading syntax. As an example, suppose we’re defining a font family to be loaded with \setmainfont{My Charis}. The corresponding MyCharis.fontspec file would contain, say,

\defaultfontfeatures[My Charis]
{
  Extension = .ttf,
  UprightFont = CharisSILR,
  BoldFont = CharisSILB,
  ItalicFont = CharisSILI,
  BoldItalicFont = CharisSILBI,
  % <any other desired options>
}

The optional argument to \defaultfontfeatures must exactly match that requested by the font loading command (\setmainfont, etc.) — in particular note that spaces are significant here, so \setmainfont{MyCharis} will not ‘see’ the default font feature setting within the .fontspec file.

\footnote{Located in the current folder or within a standard texmf location.}
Finally, note that options for individual font faces can also be defined in this way. To continue the example above, here we colour the different faces:

\defaultfontfeatures[CharisSILR]{Color=blue}
\defaultfontfeatures[CharisSILB]{Color=red}

Such configuration lines could be stored either inline inside My Charis.fontspec or within their own .fontspec files; in this way, fontspec is designed to handle 'nested' configuration options.

Where \defaultfontfeatures is being used to specify font faces by a custom name, the Font feature is used to set the filename of the font face. For example:

\defaultfontfeatures[charis]{
  UprightFont = charis-regular,
  % <other desired options for all font faces in the family>
}
\defaultfontfeatures[charis-regular]{
  Font = CharisSILR
  % <other desired options just for the `upright' font>
}

The fontspec interface here is designed to be flexible to accommodate a variety of use cases; there is more than one way to achieve the same outcome when font faces are collected together into a larger font family.

2.4 Querying whether a font ‘exists’

The conditional \IfFontExistsTF is provided to test whether the ⟨font name⟩ exists or is loadable. If it is, the ⟨true branch⟩ code is executed; otherwise, the ⟨false branch⟩ code is.

This command can be slow since the engine may resort to scanning the filesystem for a missing font. Nonetheless, it has been a popular request for users who wish to define ‘fallback fonts’ for their documents for greater portability.

In this command, the syntax for the ⟨font name⟩ is a restricted/simplified version of the font loading syntax used for \fontspec and so on. Fonts to be loaded by filename are detected by the presence of an appropriate extension (.otf, etc.), and paths should be included inline. E.g.:

\IfFontExistsTF{cmr10}{T}{F}
\IfFontExistsTF{Times New Roman}{T}{F}
\IfFontExistsTF{tergyrepagella-regular.otf}{T}{F}
\IfFontExistsTF{/Users/will/Library/Fonts/CODE2000.TTF}{T}{F}

The \IfFontExistsTF command is a synonym for the programming interface function \fontspec_font_if_exist:nTF (Section 5 on page 68).
3 Commands to select font families

For cases when a specific font with a specific feature set is going to be re-used many times in a document, it is inefficient to keep calling `\fontspec` for every use. While the `\fontspec` command does not define a new font instance after the first call, the feature options must still be parsed and processed.

For this reason, new commands can be created for loading a particular font family with the `\newfontfamily` command and variants, outlined in Section 1 on page 9 and demonstrated in Example 2. This macro should be used to create commands that would be used in the same way as `\rmfamily`, for example. If you would like to create a command that only changes the font inside its argument (i.e., the same behaviour as `\emph`) define it using regular \LaTeX commands:

```latex
\newcommand{\textnote}[1]{{\notefont #1}}
\textnote{This is a note.}
```

Note that the double braces are intentional; the inner pair is used to delimit the scope of the font change.

Comment for advanced users: The commands defined by `\newfontfamily` (and `\newfontface`; see next section) include their encoding information, so even if the document is set to use a legacy \TeX encoding, such commands will still work correctly. For example,

```latex
\documentclass{article}
\usepackage{fontspec}
\newfontfamily{unicodefont}{Lucida Grande}
\usepackage{mathpazo}
\usepackage[T1]{fontenc}
\begin{document}
A legacy \TeX\ font. {\unicodefont A unicode font.}
\end{document}
```

4 Commands to select single font faces

```
\newfontface{cmd}{{font}}{{font features}}
\setfontface{cmd}{{font}}{{font features}}
\renewfontface{cmd}{{font}}{{font features}}
\providefontface{cmd}{{font}}{{font features}}
```

Sometimes only a specific font face is desired, without accompanying italic or bold variants being automatically selected. This is common when selecting a fancy italic font, say, that has swash features unavailable in the upright forms. `\newfontface` is used for this purpose, shown in Example 3, which is repeated in Section 3.4 on page 61.

---

Example 2: Defining new font families.

```
\newfontfamily{notefont}{Kurier}
\notefont This is a \emph{note}.
```

14
4.1 More control over font shape selection

<table>
<thead>
<tr>
<th>BoldFont = ⟨font name⟩</th>
</tr>
</thead>
<tbody>
<tr>
<td>ItalicFont = ⟨font name⟩</td>
</tr>
<tr>
<td>BoldItalicFont = ⟨font name⟩</td>
</tr>
<tr>
<td>SlantedFont = ⟨font name⟩</td>
</tr>
<tr>
<td>BoldSlantedFont = ⟨font name⟩</td>
</tr>
<tr>
<td>SmallCapsFont = ⟨font name⟩</td>
</tr>
<tr>
<td>UprightFont = ⟨font name⟩</td>
</tr>
</tbody>
</table>

The automatic bold, italic, and bold italic font selections will not be adequate for the needs of every font: while some fonts mayn’t even have bold or italic shapes, in which case a skilled (or lucky) designer may be able to chose well-matching accompanying shapes from a different font altogether, others can have a range of bold and italic fonts to chose among. The BoldFont and ItalicFont features are provided for these situations. If only one of these is used, the bold italic font is requested as the default from the new font. See Example 4.

If a bold italic shape is not defined, or you want to specify both custom bold and italic shapes, the BoldItalicFont feature is provided.

4.1.1 Small caps and slanted font shapes

When a font family has both slanted and italic shapes, these may be specified separately using the analogous features SlantedFont and BoldSlantedFont. Without these, however, the \LaTeX{} font switches for slanted (\textsl{}, \textslshape) will default to the italic shape.

Pre-OpenType, it was common for font families to be distributed with small caps glyphs in separate fonts, due to the limitations on the number of glyphs allowed in the PostScript Type 1 format. Such fonts may be used by declaring the SmallCapsFont of the family you are specifying:

\begin{verbatim}
\setmainfont{Minion MM Roman}{
  SmallCapsFont={Minion MM Small Caps & Oldstyle Figures}
}\end{verbatim}

Example 4: Explicit selection of the bold font.
Roman 123 \\ \textsc{Small caps 456}

In fact, you should specify the small caps font for each individual bold and italic shape as in

\setmainfont{ <upright> }{[
  UprightFeatures = { SmallCapsFont={ <sc> } },
  BoldFeatures = { SmallCapsFont={ <bf sc> } },
  ItalicFeatures = { SmallCapsFont={ <it sc> } },
  BoldItalicFeatures = { SmallCapsFont={ <bf it sc> } },
]
Roman 123 \\ \textsc{Small caps 456}

For most modern fonts that have small caps as a font feature, this level of control isn’t generally necessary. All of the bold, italic, and small caps fonts can be loaded with different font features from the main font. See Section 3 for details. When an OpenType font is selected for SmallCapsFont, the small caps font feature is not automatically enabled. In this case, users should write instead, if necessary,

\setmainfont{...}{[
  SmallCapsFont={...},
  SmallCapsFeatures={Letters=SmallCaps},
]

4.2 Specifically choosing the NFSS family

In \LaTeX’s NFSS, font families are defined with names such as ‘ppl’ (Palatino), ‘lmr’ (Latin Modern Roman), and so on, which are selected with the \texttt{\fontfamily} command:

\texttt{\fontfamily{ppl}\selectfont}

In fontspec, the family names are auto-generated based on the fontname of the font; for example, writing \texttt{\fontspec{Times New Roman}} for the first time would generate an internal font family name of ‘TimesNewRoman(1)’. Please note that you should not rely on the name that is generated.

In certain cases it is desirable to be able to choose this internal font family name so it can be re-used elsewhere for interacting with other packages that use the \LaTeX’s font selection interface; an example might be

\usepackage{fancyvrb}\fvset{fontfamily=myverbatimfont}

To select a font for use in this way in fontspec use the NFSSFamily feature:\footnote{Thanks to Luca Fascione for the example and motivation for finally implementing this feature.}

\newfontfamily\verbatimfont[NFSSFamily=myverbatimfont]{Inconsolata}

It is then possible to write commands such as:

\texttt{\fontfamily{myverbatimfont}\selectfont}
which is essentially the same as writing \verbatimfont, or to go back to the original example:
\verbatimfont

Only use this feature when necessary; the in-built font switching commands that fontspec generates (such as \verbatimfont in the example above) are recommended in all other cases.

If you don’t wish to explicitly set the nsss family but you would like to know what it is, an alternative mechanism for package writers is introduced as part of the fontspec programming interface; see the function \fontspec_set_family:Nnn for details (Section 5 on page 68).

4.3 Choosing additional nsss font faces

\LaTeX's font selection scheme (nsss) is more flexible than the fontspec interface discussed up until this point. It assigns to each font face a family (discussed above), a series such as bold or light or condensed, and a shape such as italic or slanted or small caps. The fontspec features such as BoldFont and so on all assign faces for the default series and shapes of the nsss, but it’s not uncommon to have font families that have multiple weights and shapes and so on.

If you set up a regular font family with the ‘standard four’ (upright, bold, italic, and bold italic) shapes and then want to use, say, a light font for a certain document element, many users will be perfectly happy to use \newfontface⟨switch⟩ and use the resulting font \⟨switch⟩. In other cases, however, it is more convenient or even necessary to load additional fonts using additional nsss specifiers.

\begin{verbatim}
FontFace = {⟨series⟩}{ ⟨shape⟩ }{ Font = ⟨font name⟩ , ⟨features⟩ }
FontFace = { ⟨series⟩}{ ⟨shape⟩}{ ⟨font name⟩ }\end{verbatim}

The font thus specified will inherit the font features of the main font, with optional additional ⟨features⟩ as requested. (Note that the optional {⟨features⟩} argument is still surrounded with curly braces.) Multiple FontFace commands may be used in a single declaration to specify multiple fonts. As an example:
\verbatimfont
\setmainfont{font1.otf}[  \FontFace = {c}{\updefault}{ font2.otf } ,  \FontFace = {c}{m}{ Font = font3.otf , Color = red } ]

Writing \fontseries{c}\selectfont will result in font2 being selected, which then followed by \fontshape{m}\selectfont will result in font3 being selected (in red). A font face that is defined in terms of a different series but an upright shape (\updefault, as shown above) will attempt to find a matching small caps feature and define that face as well. Conversely, a font face defined in terms of a non-standard font shape will not.

There are some standards for choosing shape and series codes; the \LaTeX font selection guide\textsuperscript{3} lists series \texttt{m} for medium, \texttt{b} for bold, \texttt{bx} for bold extended, \texttt{sb} for semi-bold, and \texttt{c} for condensed. A far more comprehensive listing is included in Appendix A of Philipp Lehman’s The Font Installation Guide\textsuperscript{4} covering 14 separate weights and 12 separate widths.

The FontFace command also interacts properly with the SizeFeatures command as follows: (nonsense set of font selection choices)

\textsuperscript{3}texdoc fntguide
\textsuperscript{4}texdoc fontinstallationguide
FontFace = {c}{n}{
  Font = Times ,
  SizeFeatures = {
    { Size = -10 , Font = Georgia } ,
    { Size = 10-15} , % default "Font = Times"
    { Size = 15- , Font = Cochin } ,
  },
},

Note that if the first Font feature is omitted then each size needs its own inner Font declaration.

4.3.1 An example for \textbf

If you wanted to set up a font family to allow nesting of the \textbf to easily access increasing font weights, you might use a declaration along the following lines:

\setmonofont{SourceCodePro}{
  Extension = .otf ,
  UprightFont = *-Light ,
  BoldFont = *-Regular ,
  FontFace = {k}{n}{*-Black} ,
}\textbf\fontdeclare{\bfseries,\fontseries{k}\selectfont}

Further ‘syntactic sugar’ is planned to make this process somewhat easier.

4.4 Math(s) fonts

When \setmainfont, \setsansfont and \setmonofont are used in the preamble, they also define the fonts to be used in maths mode inside the \textit-type commands. This only occurs in the preamble because \LaTeX freezes the maths fonts after this stage of the processing. The fontspec package must also be loaded after any maths font packages (e.g., euler) to be successful. (Actually, it is only euler that is the problem.\footnote{Speaking of euler, if you want to use its \textit option, it won’t work, and you’ll need to put this after fontspec is loaded instead: \AtBeginDocument{\DeclareMathAlphabet\mathbf{U}{eur}{b}{n}}} )

Note that fontspec will not change the font for general mathematics; only the upright and bold shapes will be affected. To change the font used for the mathematical symbols, see either the mathspec package or the unicode-math package.

Note that you may find that loading some maths packages won’t be as smooth as you expect since fontspec (and \LaTeX in general) breaks many of the assumptions of \LaTeX as to where maths characters and accents can be found. Contact me if you have troubles, but I can’t guarantee to be able to fix any incompatibilities. The Lucida and Euler maths fonts should be fine; for all others keep an eye out for problems.
However, the default text fonts may not necessarily be the ones you wish to use when typesetting maths (especially with the use of fancy ligatures and so on). For this reason, you may optionally use the commands above (in the same way as our other \fontspec-like commands) to explicitly state which fonts to use inside such commands as \texttt{\texttt{mathrm}}. Additionally, the \texttt{\texttt{setboldmathrm}} command allows you define the font used for \texttt{\texttt{mathrm}} when in bold maths mode (which is activated with, among others, \texttt{\texttt{boldmath}}).

For example, if you were using Optima with the Euler maths font, you might have this in your preamble:

\begin{verbatim}
\usepackage{mathpazo}
\usepackage{fontspec}
\setmainfont{Optima}
\setmathrm{Optima}
\setboldmathrm{BoldFont={Optima ExtraBlack}}{Optima Bold}
\end{verbatim}

These commands are compatible with the \texttt{unicode-math} package. Having said that, \texttt{unicode-math} also defines a more general way of defining fonts to use in maths mode, so you can ignore this subsection if you’re already using that package.

\section{Miscellaneous font selecting details}

The optional argument — from Version 2.4

For the first decade of \fontspec’s life, optional font features were selected with a bracketed argument before the font name, as in:

\begin{verbatim}
\setmainfont{myfont.otf}[
  lots and lots,
  and more and more,
  an excessive number really,
  of font features could go here
]{myfont.otf}
\end{verbatim}

This always looked like ugly syntax to me, because the most important detail — the name of the font — was tucked away at the end. The order of these arguments has now been reversed:

\begin{verbatim}
\setmainfont{myfont.otf}[
  lots and lots,
  and more and more,
  an excessive number really,
  of font features could go here
]
\end{verbatim}

I hope this doesn’t cause any problems.

1. Backwards compatibility has been preserved, so either input method works.

2. In fact, you can write

\begin{verbatim}
\fontspec[ Ligatures=Rare]{myfont.otf}[Color=red]
\end{verbatim}

if you really felt like it and both sets of features would be applied.
3. Following standard \texttt{xparse} behaviour, there must be no space before the opening bracket; writing

\begin{verbatim}
\fontspec{myfont.otf} \[Color=red]
\end{verbatim}

will result in \texttt{[Color=red]} not being recognised an argument and therefore it will be typeset as text. When breaking over lines, write either of:

\begin{verbatim}
\fontspec{myfont.otf} \%
\fontspec{myfont.otf}
\end{verbatim}

\begin{verbatim}
\fontspec{myfont.otf} [Color=red]
\fontspec{myfont.otf}[Color=Red]
\end{verbatim}

Spaces \texttt{\fontspec{...}} and \texttt{\addfontfeatures} ignore trailing spaces as if it were a `naked' control sequence; e.g., `M. \fontspec{...} N' and `M. \fontspec{...}N' are the same.
Part III
Selecting font features

The commands discussed so far such as \fontspec each take an optional argument for accessing the font features of the requested font. Commands are provided to set default features to be applied for all fonts, and even to change the features that a font is presently loaded with. Different font shapes can be loaded with separate features, and different features can even be selected for different sizes that the font appears in. This part discusses these options.

1 Default settings

\defaultfontfeatures{(font features)}

It is sometimes useful to define font features that are applied to every subsequent font selection command. This may be defined with the \defaultfontfeatures command, shown in Example 5. New calls of \defaultfontfeatures overwrite previous ones, and defaults can be reset by calling the command with an empty argument.

\defaultfontfeatures[(font name)]{(font features)}

Default font features can be specified on a per-font and per-face basis by using the optional argument to \defaultfontfeatures as shown.

\defaultfontfeatures[texgyreadventor-regular.otf]{Color=blue}
\setmainfont{texgyreadventor-regular.otf}% will be blue

Multiple fonts may be affected by using a comma separated list of font names.

\defaultfontfeatures[(font-switch)]{(font features)}

New in v2.4. Defaults can also be applied to symbolic families such as those created with the \newfontfamily command and for \rmfamily, \sffamily, and \ttfamily:

\defaultfontfeatures[\rmfamily,\sffamily]{Ligatures=TeX}
\setmainfont{texgyreadventor-regular.otf}% will use standard TeX ligatures

Example 5: A demonstration of the \defaultfontfeatures command.

\fontspec{texgyreadventor-regular.otf}
Some default text 0123456789 \$ackslash$ \\
\defaultfontfeatures{
  Numbers=OldStyle, Color=888888 
}
\fontspec{texgyreadventor-regular.otf}
Now grey, with old-style figures: 0123456789

Some default text 0123456789
Now grey, with old-style figures: 0123456789
The line above to set \TeX-like ligatures is now activated by default in fontspec.cfg. To reset
default font features, simply call the command with an empty argument:

\defaultfontfeatures[\rmfamily,\sffamily]{}
\setmainfont{texgyreadventor-regular.otf}% will no longer use standard \TeX ligatures

\defaultfontfeatures+\{⟨font features⟩\}
\defaultfontfeatures+\{⟨font name⟩\}\{⟨font features⟩\}

New in v2.4. Using the + form of the command appends the ⟨font features⟩ to any
already-selected defaults.

2 Working with the currently selected features

\IfFontFeatureActiveTF{⟨font feature⟩}\{⟨true code⟩\}\{⟨false code⟩\}

This command queries the currently selected font face and executes the appropriate
branch based on whether the ⟨font feature⟩ as specified by fontspec is currently active.

For example, the following will print 'True':

\setmainfont{texgyrepagella-regular.otf}[Numbers=OldStyle]
\IfFontFeatureActiveTF{Numbers=OldStyle}{True}{False}

Note that there is no way for fontspec to know what the default features of a font will
be. For example, by default the texgyrepagella fonts use lining numbers. But in the follow-
ing example, querying for lining numbers returns false since they have not been explicitly
requested:

\setmainfont{texgyrepagella-regular.otf}
\IfFontFeatureActiveTF{Numbers=Lining}{True}{False}

Please note: At time of writing this function only supports OpenType fonts; AAT/Graphite
fonts under the Xe\LaTeX engine are not supported.

\addfontfeatures\{⟨font features⟩\}

This command allows font features to be changed without knowing what features are
currently selected or even what font is being used. A good example of this could be to add
a hook to all tabular material to use monospaced numbers, as shown in Example 6. If you
attempt to change an already-selected feature, fontspec will try to de-activate any features
that clash with the new ones. E.g., the following two invocations are mutually exclusive:

\addfontfeature{Numbers=OldStyle}...
\addfontfeature{Numbers=Lining}...

Since Numbers=Lining comes last, it takes precedence and deactivates the call Numbers=OldStyle.

This command may also be executed under the alias \addfontfeature.
Example 6: A demonstration of the `\addfontfeatures` command.

\begin{tabular}{@{} cccc @{}}
\hline
Year & People & Miles & Boats \\
1842 & 999 & 75 & 13 \\
1923 & 111 & 54 & 56 \\
\hline
\end{tabular}

\begin{verbatim}
\fontspec{texgyreadventor-regular.otf}\%
[Numbers={Proportional,OldStyle}]
'In 1842, 999 people sailed 97 miles in
13 boats. In 1923, 111 people sailed 54
miles in 56 boats.' \bigskip
\addfontfeatures{Numbers={Monospaced,Lining}}
\begin{tabular}{@{} cccc @{}}
\hline
Year & People & Miles & Boats \\
1842 & 999 & 75 & 13 \\
1923 & 111 & 54 & 56 \\
\hline
\end{tabular}
\end{verbatim}

2.1 Priority of feature selection

Features defined with `\addfontfeatures` override features specified by `\fontspec`, which in turn override features specified by `\defaultfontfeatures`. If in doubt, whenever a new font is chosen for the first time, an entry is made in the transcript (`.log`) file displaying the font name and the features requested.

3 Different features for different font shapes

<table>
<thead>
<tr>
<th>BoldFeatures={⟨features⟩}</th>
<th>ItalicFeatures={⟨features⟩}</th>
<th>BoldItalicFeatures={⟨features⟩}</th>
<th>SlantedFeatures={⟨features⟩}</th>
<th>BoldSlantedFeatures={⟨features⟩}</th>
<th>SmallCapsFeatures={⟨features⟩}</th>
<th>UprightFeatures={⟨features⟩}</th>
</tr>
</thead>
</table>

It is entirely possible that separate fonts in a family will require separate options; e.g., Hoefler Text Italic contains various swash feature options that are completely unavailable in the upright shapes.

The font features defined at the top level of the optional `\fontspec` argument are applied to all shapes of the family. Using `Upright-`, `SmallCaps-`, `Bold-`, `Italic-`, and `BoldItalicFeatures`, separate font features may be defined to their respective shapes in addition to, and with precedence over, the global font features. See Example 7.

Note that because most fonts include their small caps glyphs within the main font, features specified with `SmallCapsFeatures` are applied in addition to any other shape-specific features as defined above, and hence `SmallCapsFeatures` can be nested within `ItalicFeatures` and friends. Every combination of upright, italic, bold and small caps can thus be assigned individual features, as shown in the somewhat ludicrous Example 8.
Example 7: Features for, say, just italics.

\fontspec{EBGaramond-Regular.otf}\
  [ItalicFont=EBGaramond-Italic.otf]
\itshape Don’t Ask Victoria! \\
\adfontfeature{ItalicFeatures={Style=Swash}}
Don’t Ask Victoria! \\

Example 8: An example of setting the SmallCapsFeatures separately for each font shape.

\fontspec{texgyretermes}[
  Extension = {.otf},
  UprightFont = {*-regular}, ItalicFont = {*-italic},
  BoldFont = {*-bold}, BoldItalicFont = {*-bolditalic},
  UprightFeatures={Color = 220022,
    SmallCapsFeatures = {Color=115511}},
  ItalicFeatures={Color = 2244FF,
    SmallCapsFeatures = {Color=112299}},
  BoldFeatures={Color = FF4422,
    SmallCapsFeatures = {Color=992211}},
  BoldItalicFeatures={Color = 888844,
    SmallCapsFeatures = {Color=444422}},
]

\Upright \textsc{Small Caps} \hfill \Upright {\textscshape Small Caps}\\
\textit{Italic} \textit{Italic \textsc{Small Caps}} \hfill \textit{Italic} {\textscshape Italic \textsc{Small Caps}}\\
\textbf{Bold} \textbf{Bold \textsc{Small Caps}} \hfill \textbf{Bold} {\textbfseries Bold \textsc{Small Caps}}\\
\textit{Bold Italic} \textit{Bold Italic \textsc{Small Caps}} \hfill \textit{Bold Italic} {\textscshape Bold Italic \textsc{Small Caps}}
4 Selecting fonts from TrueType Collections (TTC files)

TrueType Collections are multiple fonts contained within a single file. Each font within a collection must be explicitly chosen using the \fontindex command. Since TrueType Collections are often used to contain the italic/bold shapes in a family, fontspec automatically selects the italic, bold, and bold italic font faces from the same file. For example, to load the macOS system font Optima:

\setmainfont{Optima.ttc}{
  Path = /System/Library/Fonts/ ,
  UprightFeatures = \{FontIndex=0\} ,
  BoldFeatures = \{FontIndex=1\} ,
  ItalicFeatures = \{FontIndex=2\} ,
  BoldItalicFeatures = \{FontIndex=3\} ,
}

Support for TrueType Collections has only been tested in Xe\TeX, but should also work with an up-to-date version of Lua\TeX\ and the luatexr package.

5 Different features for different font sizes

\begin{quote}
\bf{SizeFeatures = { \}
  ...
  \{ Size = \{size range\} , \{font features\} \},
  \{ Size = \{size range\} , Font = \{font name\} , \{font features\} \},
  ...
}\end{quote}

The SizeFeature feature is a little more complicated than the previous features discussed. It allows different fonts and different font features to be selected for a given font family as the point size varies.

It takes a comma separated list of braced, comma separated lists of features for each size range. Each sub-list must contain the Size option to declare the size range, and optionally the Font option to change the font based on size. Other (regular) fontspec features that are added are used on top of the font features that would be used anyway. A demonstration to clarify these details is shown in Example 9. A less trivial example is shown in the context of optical font sizes in Section 6.6 on page 30.

To be precise, the Size sub-feature accepts arguments in the form shown in Table 1 on the next page. Braces around the size range are optional. For an exact font size (Size=X) font sizes chosen near that size will ‘snap’. For example, for size definitions at exactly 11pt and 14pt, if a 12pt font is requested \textit{actually} the 11pt font will be selected. This is a remnant of the past when fonts were designed in metal (at obviously rigid sizes) and later when bitmap fonts were similarly designed for fixed sizes.

If additional features are only required for a single size, the other sizes must still be specified. As in:

\begin{quote}
\texttt{SizeFeatures=\{}
  \{Size=-10,Numbers=Uppercase\},
  \{Size=10-\}}
\end{quote}
Example 9: An example of specifying different font features for different sizes of font with SizeFeatures.

\fontspec{texgyrechorus-mediumitalic.otf}{
  SizeFeatures={
    {Size={-8}, Font=texgyrebonum-italic.otf, Color=AA0000},
    {Size={8-14}, Color=00AA00},
    {Size={14-}, Color=0000AA}}
}

\scriptsize Small
Normal size
\Large Large

Otherwise, the font sizes greater than 10 won’t be defined at all!

Interaction with other features  For SizeFeatures to work with ItalicFeatures, BoldFeatures, etc., and SmallCapsFeatures, a strict hierarchy is required:

UprightFeatures =
{  SizeFeatures =
  {   
    Size = -10,  
    Font = ..., % if necessary  
    SmallCapsFeatures = {...},  
    ... % other features for this size range  
  },  
  ... % other size ranges  
}

Suggestions on simplifying this interface welcome.

6 Font independent options

Features introduced in this section may be used with any font.

<table>
<thead>
<tr>
<th>Input</th>
<th>Font size, $s$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size = $X$-</td>
<td>$s \geq X$</td>
</tr>
<tr>
<td>Size = $-Y$</td>
<td>$s &lt; Y$</td>
</tr>
<tr>
<td>Size = $X-Y$</td>
<td>$X \leq s &lt; Y$</td>
</tr>
<tr>
<td>Size = $X$</td>
<td>$s = X$</td>
</tr>
</tbody>
</table>
6.1 Colour

Color (or Colour) uses font specifications to set the colour of the text. You should think of this as the literal glyphs of the font being coloured in a certain way. Notably, this mechanism is different to that of the color/xcolor/hyperref/etc. packages, and in fact using fontsize commands to set colour will prevent your text from changing colour using those packages at all! For example, if you set the colour in a \setmainfont command, \color{...} and related commands, including hyperlink colouring, will no longer have any effect on text in this font.) Therefore, fontsize’s colour commands are best used to set explicit colours in specific situations, and the xcolor package is recommended for more general colour functionality.

The colour is defined as a triplet of two-digit Hex RGB values, with optionally another value for the transparency (where 00 is completely transparent and FF is opaque.) Transparency is supported by LuaLaTeX; XeLaTeX with the xdvipdfmx driver does not support this feature.

If you load the xcolor package, you may use any named colour instead of writing the colours in hexadecimal.

\usepackage{xcolor}
...
\fontsize{48}{48}
\selectfont
\definecolor{mycolor}{rgb}{0.3,0.4,0.5}
\selectfont
\color{mycolor}

The color package is not supported; use xcolor instead.

You may specify the transparency with a named colour using the Opacity feature which takes an decimal from zero to one corresponding to transparent to opaque respectively:

\fontsize{48}{48}
\selectfont
\definecolor{mycolor}{rgb}{0.3,0.4,0.5}
\selectfont
\color{mycolor,Opacity=0.7}

It is still possible to specify a colour in six-char hexadecimal form while defining opacity in this way, if you like.

6.2 Scale

In its explicit form, Scale takes a single numeric argument for linearly scaling the font, as demonstrated in Example 1.

Example 10: Selecting colour with transparency.

\fontsize{48}{48}
\selectfont
\definecolor{mycolor}{rgb}{0.3,0.4,0.5}
\selectfont
\color{mycolor,Opacity=0.7}
As well as a numerical argument, the `Scale` feature also accepts options `MatchLowercase` and `MatchUppercase`, which will scale the font being selected to match the current default roman font to either the height of the lowercase or uppercase letters, respectively; these features are shown in Example 11. The amount of scaling used in each instance is reported in the `.log` file.

Additional calls to the `Scale` feature overwrite the settings of the former. If you want to accumulate scale factors (useful perhaps to fine-tune the settings of `MatchLowercase`), the `ScaleAgain` feature can be used as many times as necessary. For example:

```
[ Scale = 1.1 , Scale = 1.2 ] % -> scale of 1.2
[ Scale = 1.1 , ScaleAgain = 1.2 ] % -> scale of 1.32
```

Note that when `Scale=MatchLowercase` is used with `\setmainfont`, the new 'main' font of the document will be scaled to match the old default. If you wish to automatically scale all fonts except have the main font use 'natural' scaling, you may write

```
\defaultfontfeatures{ Scale = MatchLowercase }
\defaultfontfeatures[\rmfamily]{ Scale = 1}
```

One or both of these lines may be placed into a local `fontspec.cfg` file (see Section 3.3 on page 6) for this behaviour to be effected in your own documents automatically. (Also see Section 1 on page 21 for more information on setting font defaults.)

### 6.3 Interword space

While the space between words can be varied on an individual basis with the \TeX primitive `\spaceskip` command, it is more convenient to specify this information when the font is first defined.

The space in between words in a paragraph will be chosen automatically, and generally will not need to be adjusted. For those times when the precise details are important, the `WordSpace` feature is provided, which takes either a single scaling factor to scale the default value, or a triplet of comma-separated values to scale the nominal value, the stretch, and the shrink of the interword space by, respectively. (`WordSpace={x}` is the same as `WordSpace={x,x,x}`).

Note that \TeX's optimisations in how it loads fonts means that you cannot use this feature in `\addfontfeatures`.

---

**Example 11:** Automatically calculated scale values.

<table>
<thead>
<tr>
<th>The perfect match is hard to find.</th>
<th>\setmainfont{Georgia} \newfontfamily\lc[Scale=MatchLowercase]{Verdana} The perfect match {\lc is hard to find.}\xdown{\newfontfamily\uc[Scale=MatchUppercase]{Arial}} L O G O F O N T</th>
</tr>
</thead>
</table>

28
6.4 Post-punctuation space

If \frenchspacing is not in effect, \TeX will allow extra space after some punctuation in its goal of justifying the lines of text. Generally, this is considered old-fashioned, but occasionally in small amounts the effect can be justified, pardon the pun.

The PunctuationSpace feature takes a scaling factor by which to adjust the nominal value chosen for the font; this is demonstrated in Example 13. Note that PunctuationSpace=0 is not equivalent to \frenchspacing, although the difference will only be apparent when a line of text is under-full.

Note that \TeX's optimisations in how it loads fonts means that you cannot use this feature in \addfontfeatures.

6.5 The hyphenation character

The letter used for hyphenation may be chosen with the HyphenChar feature. With one exception (HyphenChar = None), this is a \LaTeX-only feature since \Lua\TeX cannot set the hyphenation character on a per-font basis; see its \texttt{\prehyphenchar} primitive for further details.

HyphenChar takes three types of input, which are chosen according to some simple rules. If the input is the string \texttt{None}, then hyphenation is suppressed for this font.

---

Example 12: Scaling the default interword space. An exaggerated value has been chosen to emphasise the effects here.

\begin{verbatim}
\fontspec{texgyretermes-regular.otf}
Some text for our example to take up some space, and to demonstrate the default interword space.
\bigskip
\fontspec{texgyretermes-regular.otf}\ [WordSpace = 0.3] Some text for our example to take up some space, and to demonstrate the default interword space.
\end{verbatim}

Example 13: Scaling the default post-punctuation space.

\begin{verbatim}
\nonfrenchspacing
\fontspec{texgyreschola-regular.otf}
Letters, Words. Sentences. \par
\fontspec{texgyreschola-regular.otf}[PunctuationSpace=2] Letters, Words. Sentences. \par
\fontspec{texgyreschola-regular.otf}[PunctuationSpace=0] Letters, Words. Sentences.
\end{verbatim}
As part of fontspec.cfg, the default monospaced family (e.g., \ttfamily) is set up to
automatically set HyphenChar = None.

If the input is a single character, then this character is used. Finally, if the input is longer
than a single character it must be the UTF-8 slot number of the hyphen character you desire.

Note that \TeX’s optimisations in how it loads fonts means that you cannot use this feature
in \addfontfeatures.

6.6 Optical font sizes

Optically scaled fonts thicken out as the font size decreases in order to make the glyph shapes
more robust (less prone to losing detail), which improves legibility. Conversely, at large optical
sizes the serifs and other small details may be more delicately rendered.

OpenType fonts with optical scaling can exist in several discrete sizes (in separate font
files). When loading fonts by name, Xe\TeX and Lua\TeX engines will attempt to automatically
load the appropriate font as determined by the current font size. An example of this behaviour
is shown in Example 15, in which some larger text is mechanically scaled down to compare
the difference for equivalent font sizes.

The OpticalSize feature may be used to specify a different optical size. With OpticalSize
set (Example 16) to zero, no optical size font substitution is performed.

The SizeFeatures feature (Section 5 on page 25) can be used to specify exactly which
optical sizes will be used for ranges of font size. For example, something like:

\fontspec{Latin Modern Roman}{
  UprightFeatures = { SizeFeatures = {
    {Size=-10, OpticalSize=8 },
    {Size= 10-14, OpticalSize=10},
    {Size= 14-18, OpticalSize=14},
    {Size= 18-, OpticalSize=18}}}
}

6.7 Font transformations

In rare situations users may want to mechanically distort the shapes of the glyphs in the cur-
rent font such as shown in Example 17. Please don’t overuse these features; they are not a
good alternative to having the real shapes.

If values are omitted, their defaults are as shown above.

---

Example 14: Explicitly choosing the hyphenation character.

\begin{verbatim}
\def\text{\fbox{\parbox{1.55cm}{\%
  EXAMPLE HYPHENATION\%}}\quad\null\par\bigskip}
\fontspec{LinLibertine_R.otf}[HyphenChar=None]\text
\fontspec{LinLibertine_R.otf}[HyphenChar={+}]\text
\end{verbatim}

30
Example 15: A demonstration of automatic optical size selection.

<table>
<thead>
<tr>
<th>Automatic optical size</th>
<th>\fontspec{Latin Modern Roman}[OpticalSize=5]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Latin Modern optical sizes [OpticalSize=8]</td>

\fontspec{Quattrocento.otf} \emph{ABCxyz} \quad \fontspec{Quattrocento.otf}[FakeSlant=0.2] ABCxyz

\fontspec{Quattrocento.otf} ABCxyz \quad \fontspec{Quattrocento.otf}[FakeStretch=1.2] ABCxyz

\fontspec{Quattrocento.otf} \textbf{ABCxyz} \quad \fontspec{Quattrocento.otf}[FakeBold=1.5] ABCxyz
If you want the bold shape to be faked automatically, or the italic shape to be slanted automatically, use the \fontspec\{AutoFakeBold\} and \fontspec\{AutoFakeSlant\} features. For example, the following two invocations are equivalent:

\fontspec[AutoFakeBold=1.5]{Charis SIL}
\fontspec[BoldFeatures={FakeBold=1.5}]{Charis SIL}

If both of the AutoFake... features are used, then the bold italic font will also be faked.

6.8 Letter spacing

Letter spacing, or tracking, is the term given to adding (or subtracting) a small amount of horizontal space in between adjacent characters. It is specified with the \fontspec\{LetterSpace\}, which takes a numeric argument, shown in Example 18.

The letter spacing parameter is a normalised additive factor (not a scaling factor); it is defined as a percentage of the font size. That is, for a 10 pt font, a letter spacing parameter of ‘1.8’ will add 0.1 pt between each letter.

This functionality is not generally used for lowercase text in modern typesetting but does have historic precedent in a variety of situations. In particular, small amounts of letter spacing can be very useful, when setting small caps or all caps titles. Also see the OpenType Uppercase option of the Letters feature (3.1.7 on page 42).

---

Example 18: The \fontspec\{LetterSpace\} feature.

\fontspec{Didot}
\addfontfeature{LetterSpace=0.0}
USE TRACKING FOR DISPLAY CAPS TEXT
\addfontfeature{LetterSpace=2.0}
USE TRACKING FOR DISPLAY CAPS TEXT

32
Part IV
OpenType

1 Introduction

OpenType fonts (and other ‘smart’ font technologies such as AAT and Graphite) can change the appearance of text in many different ways. These changes are referred to as font features. When the user applies a feature — for example, small capitals — to a run of text, the code inside the font makes appropriate substitutions and small capitals appear in place of lowercase letters. However, the use of such features does not affect the underlying text. In our small caps example, the lowercase letters are still stored in the document; only the appearance has been changed by the OpenType feature. This makes it possible to search and copy text without difficulty. If the user selected a different font that does not support small caps, the ‘plain’ lowercase letters would appear instead.

Some OpenType features are required to support particular scripts, and these features are often applied automatically. The Indic scripts, for example, often require that characters be reshaped and reordered after they are typed by the user, in order to display them in the traditional ways that readers expect. Other features can be applied to support a particular language. The Junicode font for medievalists uses by default the Old English shape of the letter thorn, while in modern Icelandic thorn has a more rounded shape. If a user tags some text as being in Icelandic, Junicode will automatically change to the Icelandic shape through an OpenType feature that localises the shapes of letters.

There are a large group of OpenType features, designed to support high quality typography a multitude of languages and writing scripts. Examples of some font features have already been shown in previous sections; the complete set of OpenType font features supported by fontspec is described below in Section 3.

The OpenType specification provides four-letter codes (e.g., smcp for small capitals) for each feature. The four-letter codes are given below along with the fontspec names for various features, for the benefit of people who are already familiar with OpenType. You can ignore the codes if they don’t mean anything to you.

1.1 How to select font features

Font features are selected by a series of \( \langle \text{feature} \rangle = \langle \text{option} \rangle \) selections. Features are (usually) grouped logically; for example, all font features relating to ligatures are accessed by writing \( \text{Ligatures}=\{\ldots\} \) with the appropriate argument(s), which could be \TeX, \Rase, etc., as shown below in 3.1.8.

Multiple options may be given to any feature that accepts non-numerical input, although doing so will not always work. Some options will override others in generally obvious ways; \( \text{Numbers}=\{\text{OldStyle}, \text{Lining}\} \) doesn’t make much sense because the two options are mutually exclusive, and \( \text{Xe}\TeX \) will simply use the last option that is specified (in this case using \text{Lining} over \text{OldStyle}).

If a feature or an option is requested that the font does not have, a warning is given in the console output. As mentioned in Section 3.4 on page 7 these warnings can be suppressed by selecting the [quiet] package option.
1.2 How do I know what font features are supported by my fonts?

Although I’ve long desired to have a feature within fontspec to display the OpenType features within a font, it’s never been high on my priority list. One reason for that is the existence of the document opentype-info.tex, which is available on CTAN or typing kpsewhich opentype-info.tex in a Terminal window. Make a copy of this file and place it somewhere convenient. Then open it in your regular \TeX editor and change the font name to the font you’d like to query; after running through plain Xe\TeX, the output PDF will look something like this:

```
OpenType Layout features found in ‘[Asana-Math.otf]’

script = 'DFLT'
  language = (default)
  features = 'onum' 'salt' 'kern'
script = 'cher'
  language = (default)
  features = 'onum' 'salt' 'kern'
script = 'grek'
  language = (default)
  features = 'onum' 'salt' 'ssty' 'kern'
script = 'latn'
  language = (default)
  features = 'dtls' 'onum' 'salt' 'ssty' 'kern'
script = 'math'
  language = (default)
  features = 'dtls' 'onum' 'salt' 'ssty' 'kern'
```

I intentionally picked a font above that by design contains few font features; ‘regular’ text fonts such as Latin Modern Roman contain many more, and I didn’t want to clutter up the document too much. After finding the scripts, languages, and features contained within the font, you’ll then need to cross-check the OpenType tags with the ‘logical’ names used by fontspec.

```

tfinfo  Alternatively, and more simply, you can use the command line tool tfinfo, which is distributed with \TeXLive. Simply type in a Terminal window, say:

    tfinfo -f `kpsewhich lromandunh1b-oblique.otf`
```

which results in:

```
aalt  Access All Alternates
cpsp  Capital Spacing
dlig  Discretionary Ligatures
frac  Fractions
kern  Kerning
liga  Standard Ligatures
lnum  Lining Figures
onum  Oldstyle Figures
```
2 OpenType scripts and languages

Fonts that include glyphs for various scripts and languages may contain different font features for the different character sets and languages they support, and different font features may behave differently depending on the script or language chosen. When multilingual fonts are used, it is important to select which language they are being used for, and more importantly what script is being used.

The ‘script’ refers to the alphabet in use; for example, both English and French use the Latin script. Similarly, the Arabic script can be used to write in both the Arabic and Persian languages.

The Script and Language features are used to designate this information. The possible options are tabulated in Table 2 on the next page and Table 3 on page 37, respectively. When a script or language is requested that is not supported by the current font, a warning is printed in the console output. See Section 2 on page 67 for methods to create new Script or Language options if required.

Because these font features can change which features are able to be selected for the font, the Script and Language settings are automatically selected by fontspec before all others, and, if Xe\TeX{} is being used, will specifically select the OpenType renderer for this font, as described in Section 1.2 on page 59.

OpenType fonts can make available different font features depending on the Script and Language chosen. In addition, these settings can also set up their own font behaviour and glyph selection (one example is differences in style between some of the letters in the alphabet used for Bulgarian, Serbian, and Russian). The fontspec feature LocalForms = Off will disable some of these substitutions if desired for some reason. It is important to note that LocalForms = On is a default not of fontspec but of the underlying font shaping engines in both Xe\TeX{} and Lua\TeX/otfload.

2.1 Script and Language examples

In the examples shown in Example 19, the Code2000 font\textsuperscript{6} is used to typeset various input texts with and without the OpenType Script applied for various alphabets. The text is only rendered correctly in the second case; many examples of incorrect diacritic spacing as well as a lack of contextual ligatures and rearrangement can be seen. Thanks to Jonathan Kew, Yves Codet and Gildas Hamel for their contributions towards these examples.

3 OpenType font features

There are a finite set of OpenType font features, and fontspec provides an interface to around half of them. Full documentation will be presented in the following sections, including how

\textsuperscript{6}http://www.code2000.net/

</table>
to enable and disable individual features, and how they interact.

A brief reference is provided (Table 4 on the next page) but note that this is an incomplete listing — only the ‘enable’ keys are shown, and where alternative interfaces are provided for convenience only the first is shown. (E.g., \texttt{Numbers=OldStyle} is the same as \texttt{Numbers=Lowercase}.)

For completeness, the complete list of OpenType features not provided with a fontspec interface is shown in Table 5 on page 40. Features omitted are partially by design and partially by oversight; for example, the \texttt{salt} feature is largely useless in \TeX{} since it is designed for providing a textscgui interface for selecting ‘all alternates’ of a glyph. Others, such as optical bounds for example, simply haven’t yet been considered due to a lack of fonts available for testing. Suggestions welcome for how/where to add these missing features to the package.

3.1 Tag-based features

3.1.1 Alternates — \texttt{salt}

The \texttt{Alternate} feature, alias \texttt{StylisticAlternates}, is used to access alternate font glyphs when variations exist in the font, such as in Example 20. It uses a numerical selection, starting from zero, that will be different for each font. Note that the \texttt{Style=Alternate} option is equivalent to \texttt{Alternate=0} to access the default case.

Note that the indexing starts from zero. With the Lua\TeX{} engine, \texttt{Alternate=Random} selects a random alternate.

See Section 1 on page 66 for a way to assign names to alternates if desired.

3.1.2 Character Variants — \texttt{cvNN}

‘Character Variations’ are selected numerically to adjust the output of (usually) a single character for the particular font. These correspond to the OpenType features \texttt{cv01} to \texttt{cv99}.

For each character that can be varied, it is possible to select among possible options for that particular glyph. For example, in the example below, variants are chosen for glyphs ‘4’ and ‘5’, and the trailing :\texttt{(n)} corresponds to which variety to choose.

\begin{verbatim}
\fontspec{EB Garamond 12 Italic}[CharacterVariant={4,5:2}] \& violet
\end{verbatim}

The numbering is entirely font-specific. Glyph ‘5’ might be the character ‘v’, for example. Character variants are specifically designed not to conflict with each other, so you can enable them individually per character. (Unlike stylistic alternates, say.) Note that the indexing starts from zero.

---

Example 20: The Alternate feature.

\begin{verbatim}
A & h \texttt{\fontspec{LinLibertine_R.otf}}\texttt{\textsc{a}} & h \texttt{\text\textsc{h}}
A \texttt{\addfontfeature{Alternate=8}} \texttt{\textsc{a}} & h
\end{verbatim}

3.1.3 Contextuals

This feature refers to substitutions of glyphs that vary 'contextually' by their relative position in a word or string of characters; features such as contextual swashes are accessed via the options shown in Table 6.

Historic forms are accessed in OpenType fonts via the feature Style=Historic; this is generally not contextual in OpenType, which is why it is not included in this feature.

3.1.4 Diacritics

Specifies how combining diacritics should be placed. These will usually be controlled automatically according to the Script setting.

3.1.5 Fractions — frac

For OpenType fonts use a regular text slash to create fractions, but the Fraction feature must be explicitly activated. Some (Asian fonts predominantly) also provide for the Alternate feature. These are both shown in Example 21.

3.1.6 Kerning — kern

Specifies how inter-glyph spacing should behave. Well-made fonts include information for how differing amounts of space should be inserted between separate character pairs. This kerning space is inserted automatically but in rare circumstances you may wish to turn it off.

As briefly mentioned previously at the end of 3.1.7, the Uppercase option will add a small amount of tracking between uppercase letters, seen in Example 22, which uses the Romande fonts (thanks to Clea F. Rees for the suggestion). The Uppercase option acts separately to the regular kerning controlled by the On/Off options.

3.1.7 Letters

The Letters feature specifies how the letters in the current font will look. OpenType fonts may contain the following options: Uppercase, Small Caps, Petite Caps, Uppercase Small Caps, Uppercase Petite Caps, and Unicase.

Petite caps are smaller than small caps. Small Caps and Petite Caps turn lowercase letters into the smaller caps letters, whereas the Uppercase... options turn the capital letters into the smaller caps (good, e.g., for applying to already uppercase acronyms like 'NASA'). This difference is shown in Example 23. 'Unicase' is a weird hybrid of upper and lower case letters.

Note that the Uppercase option will (probably) not actually map letters to uppercase. It is designed to select various uppercase forms for glyphs such as accents and dashes, such as shown in Example 24; note the raised position of the hyphen to better match the surrounding letters.

The Kerning feature also contains an Uppercase option, which adds a small amount of spacing in between letters (see 3.1.6 on page 40).

---

Example 22: Adding extra kerning for uppercase letters. (The difference is usually very small.)

```latex
\fontspec{RomandeADFStd-DemiBold.otf}
UPPERCASE EXAMPLE \addfontfeature{Kerning=Uppercase}
UPPERCASE EXAMPLE
```

---

7 http://arkandis.tuxfamily.org/adffonts.html
8 If you want automatic uppercase letters, look to \LaTeX\ \texttt{\MakeUppercase} command.

\texttt{\fontspec{LinLibertine_R.otf}\addfontfeature{Letters=Uppercase}}
3.1.8 Ligatures

Ligatures refer to the replacement of two separate characters with a specially drawn glyph for functional or aesthetic reasons. The list of options, of which multiple may be selected at one time, is shown in Table 11. A demonstration with the Linux Libertine fonts\(^9\) is shown in Example 25.

Note the additional features accessed with Ligatures=TeX. These are not actually real OpenType features, but additions provided by luaotfload (i.e., Lua\TeX{} only) to emulate \TeX{}’s behaviour for \texttt{ascii} input of curly quotes and punctuation. In X\LaTeX{} this is achieved with the \texttt{Mapping} feature (see Section 1.1 on page 59) but for consistency Ligatures=TeX will perform the same function as \texttt{Mapping=\textit{tex-text}}.

3.1.9 Localised Forms — \texttt{locl}

This feature enables and disables glyph substitutions, etc., that are specific to the Language selected in the font. This feature is automatically activated by default when present, so it should not be generally necessary to use LocalForms = \texttt{On}. In certain scenarios it may be important to turn it \texttt{Off} (although nothing specifically springs to mind).

3.1.10 Numbers

The Numbers feature defines how numbers will look in the selected font, accepting options shown in Table 13.

The synonyms \texttt{Uppercase} and \texttt{Lowercase} are equivalent to \texttt{Lining} and \texttt{OldStyle}, respectively. The differences have been shown previously in Section 2 on page 22. The \texttt{Monospaced} option is useful for tabular material when digits need to be vertically aligned.

The \texttt{SlashedZero} option replaces the default zero with a slashed version to prevent confusion with an uppercase ‘O’, shown in Example 26.

The \texttt{Arabic} option (with tag \texttt{anum}) maps regular numerals to their Arabic script or Persian equivalents based on the current Language setting (see Section 2 on page 35). This option is based on a Lua\TeX{} feature of the luaotfload package, not an OpenType feature. (Thus, this feature is unavailable in X\LaTeX{}.) This feature should be considered deprecated; while there are

45
no plans to remove it from this package, if its support is dropped from the font loader it could disappear from fontspec with little notice.

3.1.11 Ornament — \ormn

Ornaments are selected with the \Ornament feature (OpenType feature \ormn), selected numerically such as for the \Annotation feature.

3.1.12 Style

‘Ruby’ refers to a small optical size, used in Japanese typography for annotations. For fonts with multiple salt OpenType features, use the fontspec \Alternate feature instead.

Example 27 shows an example of a font feature that involves glyph substitution for particular letters within an alphabet. Other options in these categories operate in similar ways, with the choice of how particular substitutions are organised with which feature largely up to the font designer.

In other features, larger breadths of changes can be seen, covering the style of an entire alphabet. See Example 28; here, the \Italic option affects the Latin text and the Ruby option the Japanese.

Note the difference here between the default and the horizontal style kana in Example 29: the horizontal style is slightly wider.

3.1.13 Stylistic Set variations — \ssNN

This feature selects a ‘Stylistic Set’ variation, which usually corresponds to an alternate glyph style for a range of characters (usually an alphabet or subset thereof). This feature is specified numerically. These correspond to OpenType features \ss01, \ss02, etc.

Two demonstrations from the Unicode font\footnote{http://junicode.sf.net} are shown in Example 30 and Example 31; thanks to Adam Buchbinder for the suggestion.

Multiple stylistic sets may be selected simultaneously by writing, e.g., \StylisticSet={1,2,3}. The \StylisticSet feature is a synonym of the Variant feature for AAT fonts. See Section 1 on page 66 for a way to assign names to stylistic sets, which should be done on a per-font basis.

3.1.14 Vertical Position

The \VerticalPosition feature is used to access things like subscript (\Inferior) and superscript (\Superior) numbers and letters (and a small amount of punctuation, sometimes). The \Ordinal option will only raise characters that are used in some languages directly after a

number. The ScientificInferior feature will move glyphs further below the baseline than
the Inferior feature. These are shown in Example 32

Numerator and Denominator should only be used for creating arbitrary fractions (see
next section).

The \texttt{realscripts} package (which is also loaded by \texttt{xlatex} for \LaTeX) redefines the \texttt{textsubscript}
and \texttt{textsuperscript} commands to use the above font features automatically, including for
use in footnote labels. If this is the only feature of \texttt{xlatex} you wish to use, consider loading
\texttt{realscripts} on its own instead.

3.2 CJK features

This section summarises the features which are largely intending for Chinese, Korean, and Japanese typesetting.

3.2.1 Annotation — nalt

Some fonts are equipped with an extensive range of numbers and numerals in different forms. These are accessed with the Annotation feature (OpenType feature nalt), selected numerically as shown in Example 33. Note that the indexing starts from zero.

3.2.2 Character width

Many Asian fonts are equipped with variously spaced characters for shoe-horning into their generally monospaced text. These are accessed through the CharacterWidth feature.

Japanese alphabetic glyphs (in Hiragana or Katakana) may be typeset proportionally, to better fit horizontal measures, or monospaced, to fit into the rigid grid imposed by ideographic typesetting. In the latter case, there are also half-width forms for squeezing more kana glyphs (which are less complex than the kanji they are amongst) into a given block of space. The same features are given to roman letters in Japanese fonts, for typesetting foreign words in the same style as the surrounding text.

The same situation occurs with numbers, which are provided in increasingly illegible compressed forms seen in Example 35.

3.2.3 CJK shape

There have been many standards for how CJK ideographic glyphs are 'supposed' to look. Some fonts will contain many alternate glyphs available in order to be able to display these glyphs correctly in whichever form is appropriate. Both AAT and OpenType fonts support the following CJKShape options: Traditional, Simplified, JIS1978, JIS1983, JIS1990, and Expert. OpenType also supports the NLC option.

3.2.4 Vertical typesetting

OpenType provides a plethora of features for accommodating the varieties of possibilities needed for vertical typesetting (CJK and others). No capabilities for achieving such vertical typesetting are provided by fontspec, however; please get in touch if there are improvements that could be made.
Part V

Commands for accents and symbols (‘encodings’)

The functionality described in this section is experimental.

In the pre-Unicode era, significant work was required by \LaTeX to ensure that input characters in the source could be interpreted correctly depending on file encoding, and that glyphs in the output were selected correctly depending on the font encoding. With Unicode, we have the luxury of a single file and font encoding that is used for both input and output.

While this may provide some illusion that we could get away simply with typing Unicode text and receive correct output, this is not always the case. For a start, hyphenation in particular is language-specific, so tags should be used when switch between languages in a document. The babel and polyglossia packages both provide features for this.

Multilingual documents will often use different fonts for different languages, not just for style, but for the more pragmatic reason that fonts do not all contain the same glyphs. (In fact, only test fonts such as Code2000 provide anywhere near the full Unicode coverage.) Indeed, certain fonts may be perfect for a certain application but miss a handful of necessary diacritics or accented letters. In these cases, fontspec can leverage the font encoding technology built into \TeX to provide on a per-font basis either provide fallback options or error messages when a desired accent or symbol is not available. However, at present these features can only be provided for input using \TeX commands rather than Unicode input; for example, typing `\`e instead of `è or `\textcopyright instead of `© in the source file.

The most widely-used encoding in \LaTeX was T1 with companion ‘TS1’ symbols provided by the textcomp package. These encodings provided glyphs to typeset text in a variety of western European languages. As with most legacy \LaTeX input methods, accents and symbols were input using encoding-dependent commands such as `\`e as described above. As of 2017, in \LaTeX on Xe\TeX and Lua\TeX, the default encoding is TU, which uses Unicode for input and output. The TU encoding provides appropriate encoding-dependent definitions for input commands to match the coverage of the T1+TS1 encodings. Wider coverage is not provided by default since (a) each font will provide different glyph coverage, and (b) it is expected that most users will be writing with direct Unicode input.

For those users who do need finer-grained control, fontspec provides an interface for a more extensible system.

1 A new Unicode-based encoding from scratch

Let’s say you need to provide support for a document originally written with fonts in the OT2 encoding, which contains encoding-dependent commands for Cyrillic letters. An example from the OT2 encoding definition file (ot2enc.def) reads:

\begin{verbatim}
\DeclareTextSymbol{\CYRIE}{OT2}{5}
\DeclareTextSymbol{\CYRDJE}{OT2}{6}
\DeclareTextSymbol{\CYRTSHE}{OT2}{7}
\DeclareTextSymbol{\cyrnje}{OT2}{8}
\end{verbatim}
To recreate this encoding in a form suitable for fontspec, create a new file named, say, `fontrange-cyr.def` and populate it with

\texttt{...}
\DeclareTextSymbol\{\CYRIE\}{\LastDeclaredEncoding}\{"0404\}
\DeclareTextSymbol\{\CYRDJE\}{\LastDeclaredEncoding}\{"0402\}
\DeclareTextSymbol\{\CYRTSHE\}{\LastDeclaredEncoding}\{"040B\}
\DeclareTextSymbol\{\cyrnje\}{\LastDeclaredEncoding}\{"045A\}
\DeclareTextSymbol\{\cyrlje\}{\LastDeclaredEncoding}\{"0459\}
\DeclareTextSymbol\{\cyrdzhe\}{\LastDeclaredEncoding}\{"045F\}
\texttt{...}

The numbers "0404, 0402, ..., are the Unicode slots (in hexadecimal) of each glyph respectively. The fontspec package provides a number of shorthands to simplify this style of input; in this case, you could also write

\texttt{\EncodingSymbol\{\CYRIE\}{\"0404\}
\texttt{...}

To use this encoding in a fontspec font, you would first add this to your preamble:

\texttt{\DeclareUnicodeEncoding\{unicyr\}{
  \input\{fontrange-cyr.def\}
}}

Then follow it up with a font loading call such as

\texttt{\setmainfont\{\ldots\}\[NFSSEncoding=unicyr\]}

The first argument unicyr is the name of the 'encoding' to use in the font family. (There's nothing special about the name chosen but it must be unique.) The second argument to \texttt{\DeclareUnicodeEncoding} also allows adjustments to be made for per-font changes. We'll cover this use case in the next section.

2 Adjusting a pre-existing encoding

There are three reasons to adjust a pre-existing encoding: to add, to remove, and to redefine some symbols, letters, and/or accents.

When adding symbols, etc., simply write

\texttt{\DeclareUnicodeEncoding\{unicyr\}{
  \input\{tuenc.def\}
  \input\{fontrange-cyr.def\}
  \EncodingSymbol\{\texttruble\}{\"20BD\}
}}
Of course if you consistently add a number of symbols to an encoding it would be a good idea to create a new `fontrange-XX.def` file to suit your needs.

When removing symbols, use the \texttt{\textbackslash UndeclareSymbol\{\textbackslash cmd\}\}} command. For example, if you a loading a font that you know is missing, say, the interrobang (not that unusual a situation), you might write:

\begin{verbatim}
\DeclareUnicodeEncoding{nobang}\{
   \input{tuenc.def}
   \UndeclareSymbol\textinterrobang
\}
\end{verbatim}

Provided that you use the command \texttt{\textinterrobang} to typeset this symbol, it will appear in fonts with the default encoding, while in any font loaded with the \texttt{nobang} encoding an attempt to access the symbol will either use the default fallback definition or return an error, depending on the symbol being undeclared.

The third use case is to redefine a symbol or accent. The most common use case in this scenario is to adjust a specific accent command to either fine-tune its placement or to 'fake' it entirely. For example, the underdot diacritic is used in typeset Sanskrit, but it is not necessarily included as an accent symbol is all fonts. By default the underdot is defined in \texttt{TU} as:

\begin{verbatim}
\EncodingAccent{\d}{"0323}
\end{verbatim}

For fonts with a missing (or poorly-spaced) "0323 accent glyph, the 'traditional' \texttt{\TeX} fake accent construction could be used instead:

\begin{verbatim}
\DeclareUnicodeEncoding{fakeacc}\{
   \input{tuenc.def}
   \EncodingCommand{\d}[1]{% 
      \hmode\bgroup
      \o@lin{elax\#1\cr\hidewidth\ltx@sh@ft{-1ex}.\hidewidth}%
      \egroup
   }
\}
\end{verbatim}

This would be set up in a document as such:

\begin{verbatim}
\newfontfamily\sanskitfont{CharisSIL}
\newfontfamily\titlefont{Posterama}[NFSSEncoding=fakeacc]
\end{verbatim}

Then later in the document, no additional work is needed:

\begin{verbatim}
...\texttt{\titlefont kalita\d m}... % <- uses fake accent
...\texttt{\sanskitfont kalita\d m}... % <- uses real accent
\end{verbatim}

To reiterate from above, typing this input with Unicode text ('kalitam') will \textit{bypass} this encoding mechanism and you will receive only what is contained literally within the font.
3 Summary of commands

The \LaTeX\ kernel provides the following font encoding commands suitable for Unicode encodings:

\begin{verbatim}
\DeclareTextCommand{(command)}{(encoding)}{(num)}{(default)}{(code)}
\DeclareUnicodeAccent{(command)}{(encoding)}{(slot)}
\DeclareTextSymbol{(command)}{(encoding)}{(letter)}{(slot)}
\DeclareTextComposite{(command)}{(encoding)}{(letter)}{(slot)}
\DeclareTextCompositeCommand{(command)}{(encoding)}{(letter)}{(code)}
\UndeclareTextCommand{(command)}{(encoding)}
\end{verbatim}

See fntguide.pdf for full documentation of these. As shown above, the following shorthands are provided by fontspec to simplify the process of defining Unicode font range encodings:

\begin{verbatim}
\EncodingCommand{(command)}{(num)}{(default)}{(code)}
\EncodingAccent{(command)}{(code)}
\EncodingSymbol{(command)}{(code)}
\EncodingComposite{(command)}{(letter)}{(slot)}
\EncodingCompositeCommand{(command)}{(letter)}{(code)}
\UndeclareSymbol{(command)}
\UndeclareAccent{(command)}
\UndeclareCommand{(command)}
\end{verbatim}
Part VI
Lua\TeX-only font features

1 Different font technologies and shapers

Lua\TeX does not directly support any font rendering technologies out of the box, it requires additional functionality to be added to properly support and control technologies such as OpenType.

Using the \texttt{Renderer} feature, there are a number of options that \texttt{fontspec} can pass to the engine to control which font technology is being used. Pre-2019, there were two options provided by \texttt{luaotfload} that generally did not require user intervention.

- \texttt{Renderer = Node}: the default ‘mode’ for typesetting OpenType fonts.
- \texttt{Renderer = Base}: a simplified mode useful only in a limited number of situations such as mathematics typesetting.

From 2019 the possibility of using the Harfbuzz text shaping engine within Lua\TeX has been developed by Khaled Hosny. When running a suitable Lua\TeX engine with Harfbuzz support, \texttt{fontspec} provides the following options:

- \texttt{Renderer = Harfbuzz}: use the Harfbuzz engine without an explicit ‘shaper’.
- \texttt{Renderer = OpenType}: use the Harfbuzz engine with the OpenType shaper.
- \texttt{Renderer = AAT}: use the Harfbuzz engine with the AAT shaper.
- \texttt{Renderer = Graphite}: use the Harfbuzz engine with the Graphite shaper.
- \texttt{Renderer = (foo)}: use the Harfbuzz engine with the \texttt{(foo)} shaper.

Support for the Harfbuzz renderer is preliminary and may be improved over time. Please treat the interface for Harfbuzz fonts as subject to change.

2 Custom font features

Lua\TeX, via the \texttt{luaotfload} package, allows the definition and re-definition of custom OpenType features for a selected font. This facility is particularly useful to implement custom substitutions or to disable unwanted but not all ligatures.

Figure 1 shows an minimal example of this type of functionality. This example creates a new OpenType feature, \texttt{oneb}, which substitutes the glyph when typesetting ‘1’ for the named glyph \texttt{one.as@1}. The glyph names are font specific and can be interrogated with third-party software such as \texttt{FontForge}.

A third-party collection of additional examples are maintained in the repository \texttt{'fonts-in-luatex'}\textsuperscript{11}. These examples are intended to correct or adjust font features in a range of commercial fonts and provide a good introduction to some of the possibilities that Lua\TeX affords.

Please refer to the Lua\TeX/\texttt{luaotfload} documentation for more details.

\textsuperscript{11}https://github.com/mewtant/fonts-in-luatex

Part VII
Fonts and features with \texttt{Xe\LaTeX}

1 \texttt{Xe\LaTeX}-only font features

The features described here are available for any font selected by \texttt{fontspec}.

1.1 Mapping

The \texttt{Mapping} feature enables a \texttt{Xe\LaTeX} text-mapping scheme, with an example shown in Example 37.

Only one mapping can be active at a time and a second call to \texttt{Mapping} will override the first. Using the \texttt{tex-text} mapping is also equivalent to writing \texttt{Ligatures=TeX}. The use of the latter syntax is recommended for better compatibility with Lua\LaTeX documents.

1.2 Different font technologies: \texttt{AAT}, \texttt{OpenType}, and \texttt{Graphite}

\texttt{Xe\LaTeX} supports three rendering technologies for typesetting, selected with the \texttt{Renderer} font feature. The first, \texttt{AAT}, is that provided only by macOS. The second, \texttt{OpenType}, is an open source OpenType interpreter. It provides greater support for OpenType features, notably contextual arrangement, over \texttt{AAT}. The third is \texttt{Graphite}, which is an alternative to OpenType with particular features for less-common languages and the capability for more powerful font options. Features for \texttt{OpenType} have already been discussed in IV on page 33; \texttt{Graphite} and \texttt{AAT} features are discussed later in Section 2 on the next page and Section 3 on the following page.

Unless you have a particular need, the \texttt{Renderer} feature is rarely explicitly required: for \texttt{OpenType} fonts, the \texttt{OpenType} renderer is used automatically, and for \texttt{AAT} fonts, \texttt{AAT} is chosen by default. Some fonts, however, will contain font tables for multiple rendering technologies, such as the Hiragino Japanese fonts distributed with macOS, and in these cases one over the other may be preferred.

Among some other font features only available through a specific renderer, \texttt{OpenType} provides for the \texttt{Script} and \texttt{Language} features, which allow different font behaviour for different alphabets and languages; see Section 2 on page 35 for the description of these features. Because these font features can change which features are able to be selected for the font instance, they are selected by \texttt{fontspec} before all others and will automatically and without warning select the \texttt{OpenType} renderer.

---

Example 37: \texttt{Xe\LaTeX}'s Mapping feature.

"¡A small amount of---text!" \texttt{\fontspec{texgyrepagella-regular.otf}[Mapping=tex-text]¡A small amount of---text!"}
1.3 Optical font sizes

Multiple Master fonts are parameterised over orthogonal font axes, allowing continuous selection along such features as weight, width, and optical size. Whereas an OpenType font will have only a few separate optical sizes, a Multiple Master font’s optical size can be specified over a continuous range. Unfortunately, this flexibility makes it harder to create an automatic interface through \texttt{\LaTeX}, and the optical size for a Multiple Master font must always be specified explicitly.

\begin{verbatim}
\fontspec{Minion MM Roman}[OpticalSize=11]
\textit{MM optical size test}
\texttt{MM optical size test}
\fontspec{Minion MM Roman}[OpticalSize=47]
\textit{MM optical size test}
\texttt{MM optical size test}
\fontspec{Minion MM Roman}[OpticalSize=71]
\textit{MM optical size test}
\texttt{MM optical size test}
\end{verbatim}

2 The Graphite renderer

Since the Graphite renderer is designed for less common scripts and languages, usually with specific or unique requirements, Graphite features are not standard across fonts. Currently \texttt{fontspec} does not support a convenient interface to select Graphite font features and all selection must be done via ‘raw’ font feature selection.

Here’s an example:

\begin{verbatim}
\fontspec{Charis SIL}[Renderer=Graphite, RawFeature={Uppercase Eng alternates=Large eng on baseline}]
\end{verbatim}

Here’s another:

\begin{verbatim}
\fontspec{AwamiNastaliq-Regular.ttf}[Renderer=Graphite] ^^^^06b5
\addfontfeature{RawFeature={Lam with V=V over bowl}} ^^^^06b5
\end{verbatim}

3 macOS’s AAT fonts

\textbf{Warning!} \texttt{Xe\LaTeX}’s implementation on macOS is currently in a state of flux and the information contained below may well be wrong from 2013 onwards. There is a good chance that the features described in this section will not be available any more as \texttt{Xe\LaTeX} completes its transition to a cross-platform–only application.

macOS’s font technology began life before the ubiquitous-OpenType era and revolved around the Apple-invented ‘\texttt{AAT}’ font format. This format had some advantages (and other disadvantages) but it never became widely popular in the font world.

Nonetheless, this is the font format that was first supported by \texttt{Xe\LaTeX} (due to its pedigree on macOS in the first place) and was the first font format supported by \texttt{fontspec}. A number of fonts distributed with macOS are still in the \texttt{AAT} format, such as ‘Skia’.
3.1 Ligatures

Ligatures refer to the replacement of two separate characters with a specially drawn glyph for functional or aesthetic reasons. For AAT fonts, you may choose from any combination of Required, Common, Rare (or Discretionary), Logos, Rebus, Diphthong, Squared, AbbrevSquared, and Icelandic.

Some other Apple AAT fonts have those 'Rare' ligatures contained in the Icelandic feature. Notice also that the old T\TeX trick of splitting up a ligature with an empty brace pair does not work in X\TeX; you must use a \opt kern or \hbox (e.g., \null) to split the characters up if you do not want a ligature to be performed (the usual examples for when this might be desired are words like ‘shelffull’).

3.2 Letters

The Letters feature specifies how the letters in the current font will look. For AAT fonts, you may choose from Normal, Uppercase, Lowercase, SmallCaps, and InitialCaps.

3.3 Numbers

The Numbers feature defines how numbers will look in the selected font. For AAT fonts, they may be a combination of Lining or OldStyle and Proportional or Monospaced (the latter is good for tabular material). The synonyms Uppercase and Lowercase are equivalent to Lining and OldStyle, respectively. The differences have been shown previously in Section 2 on page 22.

3.4 Contextuals

This feature refers to glyph substitution that vary by their position; things like contextual swashes are implemented here. The options for AAT fonts are WordInitial, WordFinal (Example 38), LineInitial, LineFinal, and Inner (Example 39, also called ‘non-final’ sometimes). As non-exclusive selectors, like the ligatures, you can turn them off by prefixing their name with No.

3.5 Vertical position

The VerticalPosition feature is used to access things like subscript (Inferior) and superscript (Superior) numbers and letters (and a small amount of punctuation, sometimes). The Ordinal option is (supposed to be) contextually sensitive to only raise characters that appear directly after a number. These are shown in Example 40.

---

Example 38: Contextual glyph for the beginnings and ends of words.

\newfontface\fancy{Hoefler Text Italic}[%
  Contextuals={WordInitial,WordFinal}]
\fancy where is all the vegemite
Example 39: A contextual feature for the 'long s' can be convenient as the character does not need to be marked up explicitly.

<table>
<thead>
<tr>
<th>'Inner' swashes can sometimes contain the archaic long s.</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{\textbackslash{}fontspec{Hoefler Text}[Contextuals=Inner]}</td>
</tr>
<tr>
<td>'Inner' swashes can sometimes contain the archaic long s.</td>
</tr>
</tbody>
</table>

Example 40: Vertical position for AAT fonts.

<table>
<thead>
<tr>
<th>Normal</th>
<th>Superior</th>
<th>Inferior</th>
<th>Ordinal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>Superior</td>
<td>Inferior</td>
<td>Ordinal</td>
</tr>
</tbody>
</table>

The \texttt{realscripts} package (also loaded by \texttt{xltexra}) redefines the \texttt{textsubscript} and \texttt{textsuperscript} commands to use the above font features, including for use in footnote labels.

### 3.6 Fractions

Many fonts come with the capability to typeset various forms of fractional material. This is accessed in \texttt{fontspec} with the \texttt{Fractions} feature, which may be turned \texttt{On} or \texttt{Off} in both AAT and OpenType fonts.

In AAT fonts, the 'fraction slash' or solidus character, is to be used to create fractions. When Fractions are turned \texttt{On}, then only pre-drawn fractions will be used. See Example 41.

Using the \texttt{Diagonal} option (AAT only), the font will attempt to create the fraction from superscript and subscript characters.

Some (Asian fonts predominantly) also provide for the \texttt{Alternate} feature shown in Example 42.

Example 41: Fractions in AAT fonts. The `\texttt{\textasciitilde\textasciitilde2044}` glyph is the 'fraction slash' that may be typed in macOS with \texttt{Opt+Shift+1}; not shown literally here due to font constraints.

<table>
<thead>
<tr>
<th>\frac{\texttt{1\textasciitilde\textasciitilde2044}}{2}</th>
<th>\frac{\texttt{5\textasciitilde\textasciitilde2044}}{6}</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\frac{1}{2}$</td>
<td>$\frac{5}{6}$</td>
</tr>
<tr>
<td>$\frac{13579\texttt{\textasciitilde\textasciitilde2044}}{24680}$</td>
<td>$\frac{13579\texttt{\textasciitilde\textasciitilde2044}}{24680}$</td>
</tr>
</tbody>
</table>

\[\texttt{\fontspec\{Fractions=On\}\{Skia\}}\]

\[\texttt{1\textasciitilde\textasciitilde2044}/2 \quad \texttt{5\textasciitilde\textasciitilde2044}/6 \quad \% \text{ fraction slash}\]

\[\texttt{\texttt{1}/2 \quad \texttt{5}/6 \quad \% \text{ regular \, slash}}\]

\[\texttt{\fontspec\{Fractions=Diagonal\}\{Skia\}}\]

\[\texttt{13579\textasciitilde\textasciitilde2044}/24680 \quad \% \text{ fraction slash}\]

\[\texttt{\texttt{\quad 13579}/24680 \quad \% \text{ regular \, slash}}\]
3.7 Variants

The Variant feature takes a single numerical input for choosing different alphabetic shapes. Don’t mind my fancy Example 43 :) I’m just looping through the nine (!) variants of Zapfino. See Section 1 on page 66 for a way to assign names to variants, which should be done on a per-font basis.

3.8 Alternates

Selection of Alternates again must be done numerically; see Example 44. See Section 1 on page 66 for a way to assign names to alternates, which should be done on a per-font basis.

3.9 Style

The options of the Style feature are defined in AAT as one of the following: Display, Engraved, IlluminatedCaps, Italic, Ruby,\textsuperscript{12} TallCaps, or TitlingCaps. Typical examples for these features are shown in 3.1.12.

3.10 CJK shape

There have been many standards for how CJK ideographic glyphs are ‘supposed’ to look. Some fonts will contain many alternate glyphs in order to be able to display these glyphs correctly in whichever form is appropriate. Both AAT and OpenType fonts support the following CJKShape options: Traditional, Simplified, JIS1978, JIS1983, JIS1990, and Expert. OpenType also supports the NLC option.

\textsuperscript{12}’Ruby’ refers to a small optical size, used in Japanese typography for annotations.

Example 42: Alternate design of pre-composed fractions.

\begin{verbatim}
\fontspec{Hiragino Maru Gothic Pro}
1/2 \quad 1/4 \quad 5/6 \quad 13579/24680 \addfontfeature{Fractions=Alternate}
\end{verbatim}

\begin{verbatim}
1/2 \quad 1/4 \quad 5/6 \quad 13579/24680
\end{verbatim}

Example 43: Nine variants of Zapfino.

\begin{verbatim}
\newcounter{var}
\whiledo{\value{var}<9}{\%
  \edef\1{\noexpand\fontspec[Variant=\thevar, Color=\thevar\thevar\thevar](Zapfino)\1%
  \makebox[0.75\width]{d}\%}
  \stepcounter{var}}
\hspace*{2cm}
\end{verbatim}

\textsuperscript{12}

Example 44: Alternate shape selection must be numerical.

\texttt{\textbackslash fontspec\{Hoefler Text Italic\}\{Alternate=0\}\textbackslash Sphinx Of Black Quartz, \{\textscshape Judge My Vow\} \textbackslash \}\\
\texttt{\textbackslash fontspec\{Hoefler Text Italic\}\{Alternate=1\}\textbackslash Sphinx Of Black Quartz, \{\textscshape Judge My Vow\}\textbackslash \}

3.11 Character width

See 3.2.2 on page 49 for relevant examples; the features are the same between OpenType and AAT fonts. AAT also allows \texttt{CharacterWidth=Default} to return to the original font settings.

3.12 Vertical typesetting

Xe\LaTeX{} provides for vertical typesetting simply with the ability to rotate the individual glyphs as a font is used for typesetting, as shown in Example 45.

No actual provision is made for typesetting top-to-bottom languages; for an example of how to do this, see the vertical Chinese example provided in the Xe\LaTeX{} documentation.

3.13 Diacritics

Diacritics are marks, such as the acute accent or the tilde, applied to letters; they usually indicate a change in pronunciation. In Arabic scripts, diacritics are used to indicate vowels. You may either choose to Show, Hide or Decompose them in AAT fonts. The Hide option is for scripts such as Arabic which may be displayed either with or without vowel markings. E.g., \texttt{\textbackslash fontspec\{Diacritics=Hide\}\{\ldots\}}

Some older fonts distributed with macOS included 'Ø' etc. as shorthand for writing 'Ø' under the label of the Diacritics feature. If you come across such fonts, you'll want to turn this feature off (imagine typing \texttt{hello/goodbye} and getting 'helløgoodbye' instead!) by decomposing the two characters in the diacritic into the ones you actually want. I recommend using the proper \LaTeX{} input conventions for obtaining such characters instead.

Example 45: Vertical typesetting.

共産主義者は

\texttt{\textbackslash fontspec\{Hiragino Mincho Pro\}\textbackslash verttext}\\
\texttt{\textbackslash fontspec\{Hiragino Mincho Pro\}\{Renderer=AAT,Vertical=RotatedGlyphs\}\textbackslash rotatebox\{-90\}\{\verttext\}}% requires the graphicx package

64
3.14 Annotation

Various Asian fonts are equipped with a more extensive range of numbers and numerals in different forms. These are accessed through the Annotation feature with the following options: Off, Box, RoundedBox, Circle, BlackCircle, Parenthesis, Period, RomanNumerals, Diamond, BlackSquare, BlackRoundSquare, and DoubleCircle.
Part VIII
Customisation and programming interface

This is the beginning of some work to provide some hooks that use fontspec for various macro programming purposes.

1 Defining new features

This package cannot hope to contain every possible font feature. Three commands are provided for selecting font features that are not provided for out of the box. If you are using them a lot, chances are I’ve left something out, so please let me know.

\newAATfeature{feature}{option}{feature code}{selector code}

Use the Xe\TeX file AAT-info.tex to obtain the code numbers. See Example 46.

New OpenType features may be created with this command:
\newopentypefeature{feature}{option}{feature tag}

The synonym \newICUfeature is deprecated.

Here’s what it would look like in practise:
\newopentypefeature{Style}{NoLocalForms}{-locl}

In case the above commands do not accommodate the desired font feature (perhaps a new \TeX feature that fontspec hasn’t been updated to support), a command is provided to pass arbitrary input into the font selection string:
\newfontfeature{name}{input string}

For example, Zapfino used to contain an AAT feature ‘Avoid d-collisions’. To access it with this package, you could do some like the following:

\newfontfeature{AvoidD}{Special= Avoid d-collisions}
\newfontfeature{NoAvoidD}{Special=!Avoid d-collisions}
\fontspec{Zapfino}[AvoidD,Variant=1]
sockdolager rubdown
\fontspec{Zapfino}[NoAvoidD,Variant=1]
sockdolager rubdown

Example 46: Assigning new aat features.

This is Xe\TeX by Jonathan Kew.

\newAATfeature{Alternate}{HoeflerSwash}{17}{1}
\fontspec{Hoefler Text Italic}[Alternate=HoeflerSwash]
This is Xe\TeX by Jonathan Kew.

66
The advantage to using the `\newAATfeature` and `\newopentypefeature` commands instead of `\newfontfeature` is that they check if the selected font actually contains the desired font feature at load time. By contrast, `\newfontfeature` will not give a warning for improper input.

2 Defining new scripts and languages

While the scripts and languages listed in Table 2 and Table 3 are intended to be comprehensive, there may be some missing; alternatively, you might wish to use different names to access scripts/languages that are already listed. Adding scripts and languages can be performed with the `\newfontscript` and `\newfontlanguage` commands. For example,

```
\newfontscript{Arabic}{arab}
\newfontlanguage{Zulu}{ZUL}
```

The first argument is the fontspec name, the second the OpenType tag. The advantage to using these commands rather than `\newfontfeature` (see Section 1 on the preceding page) is the error-checking that is performed when the script or language is requested.

Both commands accept a comma-separated list of OpenType tags in order of preference. This permits, for example, supporting both new and old versions of a language tag with a common user interface:

```
\newfontlanguage{Turkish}{TRK,TUR}
```

Here, a font that is requested with `Script=Turkish` will first be checked for the OpenType language tag `TRK`, which will be selected if available. If not available, the `TUR` tag will be queried and used if possible as a fallback.

3 Going behind fontspec’s back

Expert users may wish not to use fontspec’s feature handling at all, while still taking advantage of its \LaTeX font selection conveniences. The \RawFeature font feature allows font feature selection using a literal feature selection string if you happen to have the OpenType feature tag memorised.

Multiple features can either be included in a single declaration:

```
[\RawFeature=+smcp;+onum]
```

or with multiple declarations:

```
[\RawFeature=+smcp, \RawFeature=+onum]
```

Example 47: Using raw font features directly.

```
\fontspec{texgyrepagella-regular.otf}[\RawFeature=+smcp]
PAGELLA SMALL CAPS
```

Pagella small caps

4 Renaming existing features & options

\aliasfontfeature If you don’t like the name of a particular font feature, it may be aliased to another with the \aliasfontfeature{(existing name)}{(new name)} command, such as shown in Example 48.

Spaces in feature (and option names, see below) are allowed. (You may have noticed this already in the lists of OpenType scripts and languages).

\aliasfontfeatureoption If you wish to change the name of a font feature option, it can be aliased to another with the command \aliasfontfeatureoption{(font feature)}{(existing name)}{(new name)}, such as shown in Example 49.

This example demonstrates an important point: when aliasing the feature options, the original feature name must be used when declaring to which feature the option belongs.

Only feature options that exist as sets of fixed strings may be altered in this way. That is, Proportional can be aliased to Prop in the Letters feature, but 550899BB cannot be substituted for Purple in a Color specification. For this type of thing, the \newfontfeature command should be used to declare a new, e.g., PurpleColor feature:

\newfontfeature{PurpleColor}{color=550899BB}

Except that this example was written before support for named colours was implemented. But you get the idea.

5 Programming interface

5.1 Variables

\l_fontspec_family_tl \l_fontspec_font In some cases, it is useful to know what the \TeX font family of a specific fontspec font is. After a \fontspec-like command, this is stored inside the \l_fontspec_family_tl macro. Otherwise, \TeX’s own \f@familymacro can be useful here, too. The raw \TeX font that is defined from the ‘base’ font in the family is stored in \l_fontspec_font.

\g_fontspec_encoding_tl Package authors who need to load fonts with legacy \TeX NFSS commands may also need to know what the default font encoding is. Since this has changed from EU1/EU2 to TU, it is best to use the variables \g_fontspec_encoding_tl or \UTFencname instead.

5.2 Functions for loading new fonts and families

\fontspec_gset_family:Nnn #1 : \TeX family \fontspec_set_family:Nnn #2 : fontspec features #3 : font name

Defines a new nsrs family from given (features) and (font), and stores the family name in the variable (family). This font family can then be selected with standard \TeX commands.

Example 48: Renaming font features.

<table>
<thead>
<tr>
<th>Roman Letters And Swash</th>
<th>\aliasfontfeature{ItalicFeatures}{IF}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Roman Letters \itshape And Swash</td>
<td>\fontspec{Hoefler Text}{IF = {Alternate=1}}</td>
</tr>
</tbody>
</table>
Example 49: Renaming font feature options.

\aliasfontfeature{VerticalPosition}{Vert Pos}
\aliasfontfeatureoption{VerticalPosition}{ScientificInferior}{Sci Inf}
\fontspec{LinLibertine_R.otf}[Vert Pos=Sci Inf]
Scientific Inferior: 12345

\fontfamily{(family)}\selectfont. See the standard fontspec user commands for applications of this function.

\fontspec_gset_fontface:NNnn \fontspec_set_fontface:NNnn
#1 : primitive font
#2 : \TeX family
#3 : fontspec features
#4 : font name

Variant of the above in which the primitive \TeX font command is stored in the variable \texttt{primitive font}. If a family is loaded (with bold and italic shapes) the primitive font command will only select the regular face. This feature is designed for \TeX programmers who need to perform subsequent font-related tests on the \texttt{primitive font}.

5.3 Conditionals

The following functions in expl3 syntax may be used for writing code that interfaces with fontspec-loaded fonts. The following conditionals are all provided in TF, T, and F forms.

5.3.1 Querying font families

\fontspec_font_if_exist:nTF Test whether the ‘font name’ (#1) exists or is loadable. The syntax of #1 is a restricted/simplified version of fontspec’s usual font loading syntax; fonts to be loaded by filename are detected by the presence of an appropriate extension (.otf, etc.), and paths should be included inline. E.g.:

\fontspec_font_if_exist:nTF {cmr10}{T}{F}
\fontspec_font_if_exist:nTF {times-new-roman}{T}{F}
\fontspec_font_if_exist:nTF {txtxyrepagella-regular.otf}{T}{F}
\fontspec_font_if_exist:nTF {/Users/will/Library/Fonts/CODE2000.TTF}{T}{F}

(End definition for \fontspec_font_if_exist:nTF. This function is documented on page ??.)

The synonym \texttt{IfFontExistsTF} is provided for ‘document authors’.

\fontspec_if_fontspec_font:TF Test whether the currently selected font has been loaded by fontspec.

(End definition for \fontspec_if_fontspec_font:TF. This function is documented on page ??.)

\fontspec_if_opentype:TF Test whether the currently selected font is an OpenType font. Always true for \LaTeX fonts.
\fontspec_if_opentype:TF  Test whether the currently selected font has a ‘small caps’ face to be selected with \texttt{\textasciitilde{}shape} or similar. Note that testing whether the font has the \texttt{Letters=SmallCaps} font feature is sufficient but not necessary for this command to return true, since small caps can also be loaded from separate font files. The logic of this command is complicated by the fact that \fontspec will merge shapes together (for italic small caps, etc.).

(End definition for \fontspec_if_opentype:TF. This function is documented on page ??.)

\fontspec_if_small_caps:TF  Test whether the currently selected font has a ‘small caps’ face to be selected with \texttt{\textasciitilde{}shape} or similar. Note that testing whether the font has the \texttt{Letters=SmallCaps} font feature is sufficient but not necessary for this command to return true, since small caps can also be loaded from separate font files. The logic of this command is complicated by the fact that \fontspec will merge shapes together (for italic small caps, etc.).

(End definition for \fontspec_if_small_caps:TF. This function is documented on page ??.)

5.3.2 Availability of features

\fontspec_if_aat_feature:nnTF  Test whether the currently selected font contains the \texttt{AAT} feature (#1,#2).

(End definition for \fontspec_if_aat_feature:nnTF. This function is documented on page ??.)

\fontspec_if_feature:nTF  Test whether the currently selected font contains the raw OpenType feature #1. E.g.: \texttt{\fontspec_if_feature:nTF \{pnum\} \{True\} \{False\}}. Returns false if the font is not loaded by fontspec or is not an OpenType font.

(End definition for \fontspec_if_feature:nTF. This function is documented on page ??.)

\fontspec_if_feature:nnnTF  Test whether the currently selected font with raw OpenType script tag #1 and raw OpenType language tag #2 contains the raw OpenType feature tag #3. E.g.: \texttt{\fontspec_if_feature:nnnTF \{latn\} \{ROM\} \{pnum\} \{True\} \{False\}}. Returns false if the font is not loaded by fontspec or is not an OpenType font.

(End definition for \fontspec_if_feature:nnnTF. This function is documented on page ??.)

\fontspec_if_script:nTF  Test whether the currently selected font contains the raw OpenType script tag #1. E.g.: \texttt{\fontspec_if_script:nTF \{latn\} \{True\} \{False\}}. Returns false if the font is not loaded by fontspec or is not an OpenType font.

(End definition for \fontspec_if_script:nTF. This function is documented on page ??.)

\fontspec_if_language:nTF  Test whether the currently selected font contains the raw OpenType language tag #1. E.g.: \texttt{\fontspec_if_language:nTF \{ROM\} \{True\} \{False\}}. Returns false if the font is not loaded by fontspec or is not an OpenType font.

(End definition for \fontspec_if_language:nTF. This function is documented on page ??.)

\fontspec_if_language:nnTF  Test whether the currently selected font contains the raw OpenType language tag #2 in script #1. E.g.: \texttt{\fontspec_if_language:nnTF \{cyril\} \{SRB\} \{True\} \{False\}}. Returns false if the font is not loaded by fontspec or is not an OpenType font.

(End definition for \fontspec_if_language:nnTF. This function is documented on page ??.)

5.3.3 Currently selected features

\fontspec_if_current_feature:nTF  Test whether the currently loaded font is using the specified raw OpenType feature tag #1. The tag string #1 should be prefixed with + to query an active feature, and with a - (hyphen) to query a disabled feature.

(End definition for \fontspec_if_current_feature:nTF. This function is documented on page ??.)

\fontspec_if_current_script:nTF  Test whether the currently loaded font is using the specified raw OpenType script tag #1.

(End definition for \fontspec_if_current_script:nTF. This function is documented on page ??.)

\fontspec_if_current_language:nTF  Test whether the currently loaded font is using the specified raw OpenType language tag #1.

(End definition for \fontspec_if_current_language:nTF. This function is documented on page ??.)
