3 Implementation 10

1 Introduction

According to the International Standards ISO 31-0:1992 to ISO 31-13:1992, superseded by ISO 80000-2:2009, mathematical constants e, i, π should be typeset in upright shape and not in italic (sloping shape) like variables (see [1] [2] [3] [4]). This package provides some tools to achieve this (automatically).

Even if it is recommended to typeset vectors names in bold italic style [2] [3], they are often represented with arrows (particularly in school documents or in physics). To draw pretty arrows above vectors, we use the esvect package by Eddie Saudrais [7] and we provide a few more macros related to vectors with arrows, in particular to improve the typesetting of the norm: $\|\overrightarrow{AB}\|$ instead of \LaTeX{} version $\|\overrightarrow{AB}\|$ which is not vertically adjusted, or worse $\|\overrightarrow{AB}\|$.

\*This document corresponds to \texttt{mismath} v1.7, dated 2019/12/27. Thanks to François Bastouil for help in English translation.
The package also provides other macros for:

- some standard operator names,
- a few useful aliases,
- improving some spacings in mathematical formulas,
- systems of equations and small matrices,
- displaymath in double columns for long calculation.

To avoid incompatibility, a large majority of our macros will be defined only if there is not another command with the same name in the packages loaded before \texttt{mismath}. If a macro is already defined, compilation will produce a warning message and \texttt{mismath} definition will simply be ignored. To keep \texttt{mismath} command, either load \texttt{mismath} before the other package with which it is in conflict for the name of the command (assuming the other package supports it), or use \texttt{\let\langle(command)\relax} before loading \texttt{mismath}.

The \texttt{amsmath} package is loaded by \texttt{mismath} without option. For using \texttt{amsmath} with options (see \cite{5}), these options can be added when calling \texttt{mismath}, or \texttt{amsmath} has to be loaded with the required options before \texttt{mismath}.

Another package, \texttt{mathtools} by Morten Høgholm and Lars Madsen \cite{6} is also loaded. It provides many useful macros.

A recommendation, seldom observed, is to typeset uppercase Greek letters in italic shape like other variables \cite{3}. This is automatically done with the \texttt{fixmath} package by Walter Schmidt \cite{9}, but this feature is not implemented in \texttt{mismath} because this rule is conflicting to the one used for instance in France where all mathematics capitals have to be typeset in upright shape\footnote{The \texttt{frenchmath} package \cite{14} takes this rule into account.}. The choice of loading or not one of these packages remains thus to the user.

\section{Usage}

\subsection{Mathematical constants}

As for classic functions identifiers, \textit{predefined} mathematical constants should be typeset in upright shape (generally in roman family), even if this practice is not really common and tedious to respect. To avoid to stuff a document with \texttt{\mathrm{e}} or \texttt{\mathit{i}} (or better \texttt{\mathup{e}} and \texttt{\mathup{i}}\footnote{\texttt{\mathup} is based on \texttt{\operatorfont} (from \texttt{amsopn} package, automatically loaded by \texttt{amsmath}). The \texttt{beamer} package uses a default sans serif math font, but \texttt{\mathrm} produces a font with serif in \texttt{beamer}. This problem is solved by using \texttt{\mathup} instead of \texttt{\mathrm}.}), the package provides \texttt{\e} command for the base of the natural logarithm and \texttt{\i} or \texttt{\j} for imaginary numbers. One can notice that \texttt{\i} and \texttt{\j} already exist in \LaTeX{}: using in LR mode, they produce “ı” and “ı” without the point so one can place accents.
Nevertheless, it can be tiresome to type a lot of backslashes in a document with many formulas containing $e$ or $i$. So a way is proposed here to free of it by placing \texttt{\enumber}, \texttt{\inumber} or \texttt{\jnumber} in the preamble: $e$, $i$ or $j$ will then automatically be set in upright shape in the whole document, no need to type \texttt{\e}, \texttt{\i} or \texttt{\j}, let’s hope that there are not many other $e$, $i$ or $j$ as variables. However, one can still get italicized $e$, $i$ or $j$ with \LaTeX command \texttt{\mathit} or \texttt{\mathnormal}. Of course, this does not fully comply with \LaTeX philosophy: in the document body, objects should be pointed out by their nature rather than their typographical characteristics, defined in the preamble. But these macros are really handy and thanks to them it is possible to bring a document up to the standards afterwards; besides anyone is free to use them or not.

Mathematical constant $\pi$ should also be typeset in upright shape (see \cite{3} and \cite{4}), which differs from italicized $\pi$. This recommendation is even less observed than the one concerning $e$ and $i$ \cite{1}. The \texttt{upgreek} package by Walter Schmidt \cite{8} makes it possible to typeset greek letters in upright font by using commands such as \texttt{\upalpha}, \texttt{\upbeta},... To avoid typing a lot of \texttt{\uppi}, we provide the \texttt{\pinumber} macro, which has to be put in the preamble. This command loads the \texttt{upgreek} package with an optional \texttt{(font)} argument: \texttt{Symbol} (by default), \texttt{Euler} or \texttt{Symbolsmallscale} (see \cite{8}). It also redefines the \texttt{\pi} command to typeset all \texttt{\pi} in the selected upright font.

By activating \texttt{\enumber}, \texttt{\inumber} and \texttt{\pinumber} in the preamble, you can get for instance:

\[ e^{i\pi} = -1 \]

When \texttt{\pinumber} is activated, the original italic $\pi$ is still available with \texttt{\itpi}.

### 2.2 Vectors

By default, the \texttt{\vect} command\footnote{As for many macros of this package, the definition will take effect only if this macro is not defined before by another package.}, produces vectors with arrows (thanks to the \texttt{esvect} package by Eddie Saudrais\footnote{\texttt{esvect} provides \texttt{\vv} macro used by \texttt{\vect}.}) which are much more elegant than those produced by \LaTeX \texttt{\overrightarrow} command (giving $\vec{AB}$). The \texttt{esvect} package has an optional argument (one letter between \texttt{a} and \texttt{h}) defining the required type of arrow (see \cite{7}). In \texttt{mismath}, \texttt{esvect} is loaded with the option \texttt{b}: \texttt{\vect{AB}} gives $\vec{AB}$. To choose another type of arrow, \texttt{esvect} must be called with the required option \texttt{before} \texttt{mismath}, for instance \texttt{\usepackage[d]{esvect}} will give the arrows produced by default in \cite{7}.

\texttt{\boldvect} \texttt{\vect} makes also possible to typeset vector’s names using bold italic (according to ISO recommendation \cite{4}) rather than arrows. For this, calling \texttt{\boldvect} will modify the behavior of \texttt{\vect}:
\[ \textbf{v} = \lambda \mathbf{e}_x + \mu \mathbf{e}_y. \]

\textbf{v} = \lambda \mathbf{e}_x + \mu \mathbf{e}_y.

By default, \texttt{\textbf{v}} uses the \texttt{\textbf{boldsymbol}} command\textsuperscript{5} from \texttt{amsbsy} package, loaded by \texttt{amsmath}. But other packages producing bold italic can be preferred, e.g. \texttt{\textbf{bm}} from \texttt{bm} package or \texttt{\textbf{mathbold}} from \texttt{fixmath} package or \texttt{\textbf{mathbfit}} from \texttt{isomath}. For that, redefine \texttt{\boldvectcommand}: for instance \texttt{\renewcommand{\boldvectcommand}{\textbf{mathbold}}}. By setting \texttt{\boldvectcommand} to \texttt{\textbf{mathbf}}, \texttt{\textbf{v}} produces vectors in bold upright shape, which tends to be used instead of bold italic (but probably for bad reasons).

\textbf{arrowvect} At any moment, you can get back to the default behavior with the inverse switch \texttt{\arrowvect}. These switches can be placed anywhere: inside mathematical mode or inside an environment (with local effect) or outside (with global effect).

\textbf{hvect} When vectors with arrows are typeset side by side, arrows can be set up a bit higher (with a vertical phantom box containing \( \mathbf{h} \)) to avoid inelegants effects:

\begin{itemize}
  \item \( \overrightarrow{AB} = \overrightarrow{u} + \overrightarrow{AC} \) is less than \( \overrightarrow{AB} = \overrightarrow{v} + \overrightarrow{AC} \), obtained with \texttt{\hvect\{u\}};
  \item \( \overrightarrow{a} \cdot \overrightarrow{b} = 0 \) is less than \( \overrightarrow{\mathbf{a}} \cdot \overrightarrow{\mathbf{b}} = 0 \), obtained with \texttt{\hvect\{a\}}.
\end{itemize}

The \texttt{\boldvect} switch has no effect on the \texttt{\hvect} macro which always typesets arrows on vectors (with the \texttt{\vv} command from the \texttt{esvect} package).

\textbf{hvec} In a similar way, \texttt{\hvec} raises the little arrow produced by the \LaTeX \ command \texttt{\textbf{vec}} (but only from height of \textit{t} letter):

\begin{itemize}
  \item \( P = \mathbf{f} \cdot \mathbf{v} \) is less than \( P = \mathbf{f} \cdot \mathbf{v} \), obtained with \texttt{\hvec\{v\}};
  \item \( \mathbf{f} = m\mathbf{\mathbf{a}} \) is less than \( \mathbf{\mathbf{f}} = m\mathbf{\mathbf{a}} \), obtained with \texttt{\hvec\{a\}}.
\end{itemize}

\textbf{norm} The norm of a vector is classically produced by the delimiters \texttt{\textbf{\textbf{\|}}\textbf{\textbf{\textbf{\textbf{|}}}}} and \texttt{\textbf{\textbf{\textbf{\|}}\textbf{\textbf{\textbf{\textbf{|}}}}} (rather than \texttt{\textbf{|}}) or \texttt{\textbf{\textbf{\textbf{\left\|}}}} and \texttt{\textbf{\textbf{\textbf{\right\|}}} for delimiters adapting to the content. Unfortunately, these delimiters are always vertically centred, relatively to the middle of the base line, whereas vectors with arrows are asymetrics objects, the height above the middle of the base line being superior to the depth under it. The code \texttt{$$\|\vec{h}\|$$} raises the double bar to produce \texttt{\|\vec{h}\|}. \texttt{Let's notice that the height of the bars don't adjust to content, but however to context: main text, subscripts or exponents.}

\textbf{2.3 Standard operator names}

\texttt{\textbf{\textbf{\di}}} The \textit{differential} operator should be typeset in upright shape and not in italic, to make it different from variables (as mentioned in [1] [2] [3] [15]). For this, we provide the \texttt{\textbf{\di}} command. See the following examples (notice the thin spaces before the \texttt{\textbf{\textbf{d}}} as for classic function's names):

\texttt{\textbf{\textbf{\\di}}\textbf{\textbf{gives}} \textbf{upright bold font, even if used in combination with \textbf{\textbf{\mathit}}.}}
\[ \iint xy \, dx \, dy \]

\[ \int \frac{d^2x}{dt^2} + h \frac{dx}{dt} + kx = 0 \]

This command can also stand for distance (hence its name):

\[ \lambda \, d(A, F) + \mu \, d(B, \mathcal{H}) \]

To refer to probability and expectation the proper use is to typeset capital letters \( \mathbb{P} \), \( \mathbb{E} \) in upright shape as for any standard function identifier. This is obtained with \( \mathbb{P} \) and \( \mathbb{E} \). Variance is normally denoted by \( \text{Var} \) (see further), but in some countries we can find \( V \) produced by \( \mathbb{V} \).

The \( \mathbb{P} \) command already existed to refer to the end of paragraph symbol \( \¶ \) and has been redefined, but this symbol can still be obtained with \( \Par \).

Some authors use “blackboard bold” font to represent probability, expectation and variance: \( \mathbb{P}, \mathbb{E}, \mathbb{V} \). The \( \texttt{probastyle} \) macro sets the appearance of \( \mathbb{P} \) and \( \mathbb{E} \) to that of standard function identifiers. Variance is normally denoted by \( \text{Var} \) (see further), but in some countries we can find \( V \) produced by \( \mathbb{V} \).

The following operator names are also defined in \texttt{mismath}:

\begin{verbatim}
\adj adj \erf erf \rank rank \\
\Aut Aut \grad grad \Re Re \\
\Conv Conv \Id id \rot rot \\
\cov cov \Id Id \sgn sgn \\
\Cov Cov \im im \span span \\
\curl curl \Im Im \tr tr \\
\divg div \lb lb \Var Var \\
\End End \lcm lcm \Zu Z \\
\end{verbatim}

By default, operators returning vectors, \( \grad \) and \( \curl \) (or its synonym \( \rot \) rather used in Europe), are written with an arrow on the top. When \texttt{boldvect} is activated, they are typeset in bold style: \( \mathbf{grad}, \mathbf{curl}, \mathbf{rot} \). For the covariance and the identity function, two notations are proposed, with or without a first capital letter, because they are both very common. On the other hand, \( \im \) stands for the imaginary part of a complex number. Notice that \( \div \) and \( \span \) already exist and haven’t been redefined, therefore the \( \divg \) and \( \spa \) macros; \( \Z \) is used otherwise (see further), therefore \( \Zu \), to designate the center of a group: \( \Z(G) \) (from German Zentrum).

\texttt{oldRe} The \( \Re \) and \( \Im \) macros already existed, to refer to real and imaginary part of a complex number, producing outdated symbols \( \Re \) and \( \Im \). They have been

\texttt{oldIm}
redefined according to actual use, as mentioned in the above table, but it’s still possible to get the old symbols with \oldRe and \oldIm.

Some (inverse) circular or hyperbolic functions, missing in \LaTeX, are also provided by \texttt{mismath}:

\begin{verbatim}
\arccot \arcsinh \arcosh \arsinh \artanh \arccsch
\sech \csch \arcosh \arsech \artanh \arcsch
\end{verbatim}

Asymptotic comparison operators (in Landau notation) are obtained with \texttt{\bigO} or \texttt{\bigo} and \texttt{\lito} commands:

\[ n^2 + \mathcal{O}(n \log n) \quad \text{or} \quad n^2 + O(n \log n) \quad \text{and} \quad e^x = 1 + x + o(x^2). \]

2.4 A few useful aliases

In the tradition of Bourbaki and D. Knuth, proper use requires that classics sets of numbers are typeset in bold roman: \texttt{\mathbf{R}}, \texttt{\mathbf{C}}, \texttt{\mathbf{Z}}, \texttt{\mathbf{N}}, \texttt{\mathbf{Q}}, “openwork” letters (\texttt{\mathbb{R}}, \texttt{\mathbb{Z}}, \ldots) being restricted to writing at blackboard [15]; and likewise to designate a field: \texttt{\mathbb{F}} or \texttt{\mathbb{K}} (Körper in German). We get these symbols with the following macros:

\begin{verbatim}
\R \C \Z \N \Q \F \K
\end{verbatim}

The \texttt{\mathset} command enables to change in a global way the behavior of all these macros: by default, \texttt{\mathset} is an alias for \texttt{\mathbf}, but if one prefer openwork letters, just place \texttt{\renewcommand\mathset{\mathbb}} in the preamble, after loading \texttt{amsfonts} package (which provides the “blackboard bold” typeface, also loaded by \texttt{amssymb}).

The \texttt{\displaystyle} command being very common, alias \texttt{\ds} is provided. Not only it eases typing but also it makes source code more readable.

Symbols with limits behave differently for in-line formulas or for displayed equations. In the latter case, “limits” are put under or above whereas for in-line math mode, they are placed on the right, as subscript or exponent. Compare: \[ \zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} \] with \[ \zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}. \]

\[ \dlim \]

With in-line math mode, displaymath behavior can be forced with \texttt{\displaystyle} or its alias \texttt{\ds}, but then, all the rest of the current mathematical environment will be set in displaymath mode too (in the previous example, the fraction will be expanded). Just like the \texttt{amsmath} command \texttt{\dfrac} only transforms the required fraction in display style, we can limit display style effect to the affected symbol, by using the following macros: \texttt{\dlim}, \texttt{\dsum}, \texttt{\dprod}, \texttt{\dcup}, \texttt{\dcap}. So \$\dlim_{x \to +\infty} \frac{1}{x}\$ gives \[ \lim_{x \to +\infty} \frac{1}{x}. \]

Large bars over expressions are obtained with \texttt{\overline} or, shorter, its alias \texttt{\lbar}. Such as for vectors, one can raise the bar (from the height of \texttt{h}) with the \texttt{\hlbar} command, in order to correct uneven bars heights.
The $\texttt{eqdef}$ macro writes equality symbol topped with “def” (thanks to the \LaTeX command \texttt{stackrel}):

\[
e^{i\theta} \texttt{def} = \cos \theta + i \sin \theta
\]

\texttt{unbr} \unbr is an alias for \texttt{underbrace}, making source code more compact.

\[
(QAP)^n = \underbrace{QAP \times QAP \times \cdots \times QAP}_{n \text{ times}}
\]

\texttt{iif} \iif is an alias for “if and only if”, to be used in text mode.

2.5 Improving some spacings in mathematical formulas

\texttt{mul} \texttt{mul} The multiplication symbol obtained with \texttt{times} produces the same spacing than addition or substraction operators, whereas division obtained with \texttt{/} is closer to its arguments. This actually hides the priority of the multiplication on + and −. This is why we provide the \texttt{mul} macro, behaving like \texttt{/} (ordinary symbol) and leaving less space around than \texttt{times}:

\[
\lambda + \alpha \times b - \beta \times c \text{ is less than } \lambda + \alpha \times b - \beta \times c, \text{ obtained with } \texttt{mul}.
\]

When using \texttt{mul} before an operator name or a \texttt{left}...\texttt{right} structure, additional spacing occur on the right side of \texttt{mul}. A solution to get the same amount of space on the two sides of \texttt{mul}, is to enclose the operator name (or the structure) with brackets:

Compare $x \times \sin x$ with $x \times \sin x$ obtained with $x \texttt{mul} \{\sin x\}$.

\texttt{then} \theen The \texttt{then} macro produces the symbol $\Rightarrow$ surrounded by large spaces as the standard macro \texttt{iif} does it with $\iff$. In a similar way, \texttt{txt} based on the \texttt{quad} macro (from the \texttt{amstext} package, automatically loaded by \texttt{amsmath}), leaves em quad spaces around the text. See the following example:

\[
\ln x = a \Rightarrow x = e^a \text{ rather than } \ln x = a \Longleftrightarrow x = e^a
\]

\texttt{paren} \paren Spaces around parenthesis produced by \texttt{left}...\texttt{right} may be too large, for example after a function name or a point name with coordinates. A solution is to add a thin negative space \texttt{!} before the opening (or after the closing) parenthesis, or to enclose the \texttt{left}...\texttt{right} structure by brackets, or to use the \texttt{paren} macro:

\[
\sin \left(\frac{\pi}{3}\right) \times 2 \text{ is less than } \sin \left(\frac{\pi}{3}\right) \times 2 \text{ obtained with } \\
\sin \texttt{paren} \{\texttt{frac}\{\pi}\{3\}\}\texttt{mul} 2.
\]

\texttt{footnote} ^8The \texttt{mathtools} package by Morten Høgholm and Lars Madsen \cite{6} provides a new improved version of \texttt{underbrace} command (as many other usefull macros); it is loaded by \texttt{mismath}.
\pow When typesetting an exponent after a closing big parenthesis produced by \right), the exponent is little to far from the parenthesis. The command \pow\{\langle expr\rangle\}\{\langle pow\rangle\} sets \langle expr\rangle between parentheses and puts the exponent \langle pow\rangle slightly closer to the right parenthesis. Compare:

\begin{equation}
e^a \sim \left(1 + \frac{a}{n}\right)^n \quad \text{and} \quad e^a \sim \left(1 + \frac{a}{n}\right)^n.
\end{equation}

\abs Absolute value (or modular for a complex number) should be typeset with \lvert...\rvert rather than | which doesn’t respect correct spaces for delimiters; for bars whose height has to adapt to content, we use \left\lvert...\right\rvert or, more simply, the \abs\{...\} command which is equivalent.

\lfrac This macro behaves like \frac but with medium spaces around the arguments, so the corresponding fraction bar is perceptibly a little bit longer:

\begin{equation}
\abs{\lfrac{\abs{z_1-z_2}}{\abs{z_1+z_2}}} \quad Z = \frac{z_1 - z_2}{z_1 + z_2}
\end{equation}

Brackets symbols [ and ] have been redefined for mathematical mode because, in standard \LaTeX, the space before them can be unsuitable:

\begin{equation}
x \in [0, \pi[ \cup ]2\pi, 3\pi[ \quad \text{without mismath}
\end{equation}

\begin{equation}
x \in [0, \pi[ \cup ]2\pi, 3\pi[ \quad \text{with mismath}
\end{equation}

In our code, [ and ] symbols are not defined anymore as delimiters. One can regret it because a line break could occur between the two, but in addition to the fact that it works very well like that for spaces (because these symbols are most of the time preceded or followed by relational, binary or punctuation symbols), it is always possible to transform them into delimiters with \left and \right.

\section{Environments for systems of equations and small matrices}

\system The system environment produces a system of equations:

\begin{equation}
\begin{cases}
x = 1 + 2t \\
y = 2 - t \\
z = -3 - t
\end{cases}
\end{equation}

This first example could also have been produced with \cases environment from \amsmath package, although \cases places mathematical expressions closer to the bracket (which makes sense considering its use). \systemsep enables to set the

\systemsep

---

9This macro gives bad results with normal sized parenthesis.

10Another solution is to define \abs with the \DeclarePairedDelimiter command from the mathtool package [6].

12Is \LaTeX definition of [ as mathopen really appropriate where this symbol could almost also logically have been defined as mathclose?
gap between the bracket and the expressions, set by default to \medspace. This gap may be reduced, for instance: \renewcommand{\systemsep}{\thinspace}, or enlarged with \thickspace (and with \renewcommand{\systemsep}{}) we get back to what cases do).

**system**[(coldef)]  
By default, a system is written like an array environment with only one column, left aligned. The environment has an optional argument to create several columns, specifying their alignment, with the same syntax than the array environment of LaTeX: \begin{system}[col1] produces a two-column system, the first one being centred, the second being left aligned, such as in the following example:

\begin{equation}
\begin{system}[c1]
y & = \dfrac{1}{2}x - 2 \\
(x, y) & \neq (0, -2)
\end{system}
\end{equation}

**systemstretch**  
Default spacing between the lines of a system environment has been slightly enlarged compared to the one from array environments (from 1.2 factor). This spacing may be changed by typing \renewcommand{\systemstretch}{⟨stretch⟩}, inside the current mathematical environment (for a local change) or outside (for a global change). By default, stretch’s value is 1.2. In addition we can use a carriage return with a spacing option such as it has been done above with \[1ex].

Another example with \begin{system}[rl@{\quad}l]  
\begin{equation}
\begin{system}[rl@{\quad}l]
x + 3y + 5z = 0 & R_1 \\
2x + 2y - z = 3 & R_2 \iff \\
3x - y + z = 2 & R_3
\end{system}
\end{equation}
\end{system}

Let’s mention the systeme package [12] which deals with linear systems with a lighter syntax and automatic alignments on +, −, =, and also the spalign package [13] which moreover produces nice alignments for matrices (with spaces and semicolons as delimiters).

**spmatrix**  
The amsmath package provides various environments to typeset matrices: for instance pmatrix surrounds the matrix with parenthesis or smallmatrix typesets a small matrix that can even be inserted in a text line. We provide a combination of the two with spmatrix:  
\begin{equation}
\begin{spmatrix}
\vec{u}
\end{spmatrix}
\end{equation}

The mathtools package enhances amsmath matrices environments and provides also a small matrix environment with parenthesis. Furthermore, with starred version \begin{psmallmatrix*}\langle col\rangle, you can choose the alignment inside the columns (c, 1 or r). But sadly, the space before the left parenthesis is too narrow regarding to the space inside the parenthesis. Compare previous \[\vec{u}(-1)\] with \[\vec{u}(-1)\].

\textsuperscript{13}@{\ldots} sets inter-column space.
2.7 Displaymath in double columns

The `mathcols` environment activates mathematical mode and enables to arrange “long” calculation in double columns, separated with a central rule, as shown in the following example. But you have to load the `multicol` package in the preamble.

\begin{mathcols}
& \frac{1}{2 \times \left(\frac{1}{4}\right)^n + 1} \geq 0.999 \iff 4^n \geq 1998 \\
& 1 \geq 1.998 \left(\frac{1}{4}\right)^n + 0.999 \iff n \ln 4 \geq \ln(1998) \\
& 0.001 \geq \frac{1.998}{4^n} \iff n \geq 6
\end{mathcols}

\begin{changecol}
The `changecol` macro causes a change of column; alignment is produced using the classic delimiters `&` and `\ \`.

\begin{changecol}
& \frac{1}{2 \times \left(\frac{1}{4}\right)^n + 1} \geq 0.999 \iff 4^n \geq 1998 \\
& 1 \geq 1.998 \left(\frac{1}{4}\right)^n + 0.999 \iff n \ln 4 \geq \ln(1998) \\
& 0.001 \geq \frac{1.998}{4^n} \iff n \geq 6
\end{changecol}

3 Implementation

1 \DeclareOption*{{{\PassOptionsToPackage{\CurrentOption}{amsmath}}} \ProcessOptions \relax
2 \@ifpackageloaded{amsmath}{\RequirePackage{amsmath}}
3 \@ifpackageloaded{esvect}{\RequirePackage{esvect}}
4 \@ifpackageloaded{ifthen}{\RequirePackage{ifthen}}
5 \RequirePackage{xspace}
6 \RequirePackage{mathtools}

The above conditional packages loading avoids “option clash” errors if the packages have been previously loaded with (other) options.

The three following internal commands are meta commands for a conditional macro definition with warning message if the macro already exists. The `\bslash` macro used inside `\@mwarning` comes from `doc.sty` package by Frank Mittelbach. It can also be used in other documents instead of `\textbackslash` (which doesn’t work here).

8 {\catcode'\|=\z@ \catcode'\\=12 |gdef|bslash{|} % the \bslash command
9 \newcommand\@mwarning[1]{
10 \PackageWarning{mismath}{

10
Command \bslash #1 already exist and will not be redefined

\newcommand\mmacro[2]{
  \@ifundefined{#1}{
    \expandafter\def\csname #1\endcsname{#2}
  }{\@mwarning{#1}}
}
\newcommand\moperator[3][\{}% this macro is ugly, TODO: by default #1=#3
  \ifthenelse{\equal{#1}{}}{
    \@ifundefined{#3}{
      \DeclareMathOperator{#2}{#3}
    }{\@mwarning{#3}}
  }{
    \@ifundefined{#1}{
      \DeclareMathOperator{#2}{#3}
    }{\@mwarning{#1}}
  }
}

To work correctly with the beamer package, we did not use \mathrm but \mathup (based on \operatorfont from the mathopn package) to produce the correct upright shape font. This command works also fine with other sans serif fonts like cmbright. Moreover for beamer, \enumber must use the family default font defined by the beamer package (sans serif), therefore the \AtBeginDocument inside the macro (otherwise it has no effect). The same holds for \inumber and \jnumber. \AtBeginDocument is also necessary to redefine \i when calling the hyperref package which overwrites the \i definition.

\providecommand{\mathup}[1][\{}{\operatorfont #1}
\newcommand{\mmacro}[2]{\mathup{#2}}
\AtBeginDocument{\let\oldi\i \let\oldj\j
  \renewcommand{\i}{\TextOrMath{\oldi}{\mathup{i}}}\renewcommand{\j}{\TextOrMath{\oldj}{\mathup{j}}}}

\DeclareSymbolFont{UpSh}{\encodingdefault}{\familydefault}{m}{n}
\newcommand{\enumber}{\AtBeginDocument{\DeclareMathSymbol{e}{\mathalpha}{UpSh}{'e}}}
\newcommand{\inumber}{\AtBeginDocument{\DeclareMathSymbol{i}{\mathalpha}{UpSh}{'i}}}
\newcommand{\jnumber}{\AtBeginDocument{\DeclareMathSymbol{j}{\mathalpha}{UpSh}{'j}}}
\newcommand*{\pinumber}[1][Symbol]{\@ifpackageloaded{greekpackage}{\usepackage[#1]{greek}}}

\end{document}
\let\itpi\pi
\renewcommand{\pi}{\uppi}
}
