Part I
User’s manual

1 Introduction

The LuaTeX-ja package is a macro package for typesetting high-quality Japanese documents when using LuaTeX.

1.1 Backgrounds

Traditionally, ASCII \( \LaTeX \), an extension of \( \TeX \), and its derivatives are used to typeset Japanese documents in \( \TeX \). \( \LaTeX \) is an engine extension of \( \TeX \): so it can produce high-quality Japanese documents without using very complicated macros. But this point is a mixed blessing: \( \LaTeX \) is left behind from other extensions of \( \TeX \), especially \( \varepsilon \LaTeX \) and pdf\( \TeX \), and from changes about Japanese processing in computers (e.g., the UTF-8 encoding).

Recently extensions of \( \LaTeX \), namely up\( \LaTeX \) (Unicode-implementation of \( \LaTeX \)) and \( \varepsilon \)-\( \LaTeX \) (merging of \( \LaTeX \) and \( \varepsilon \)-\( \LaTeX \) extension), have developed to fill those gaps to some extent, but gaps still exist.

However, the appearance of Lua\( \TeX \) changed the whole situation. With using Lua "callbacks", users can customize the internal processing of Lua\( \TeX \). So there is no need to modify sources of engines to support Japanese typesetting: to do this, we only have to write Lua scripts for appropriate callbacks.

1.2 Major changes from \( \LaTeX \)

The Lua\( \TeX \)-ja package is under much influence of \( \LaTeX \) engine. The initial target of development was to implement features of \( \LaTeX \). However, implementing all feature of \( \LaTeX \) is impossible, since all process of Lua\( \TeX \)-ja must be implemented only by Lua and \( \TeX \) macros. Hence Lua\( \TeX \)-ja is not a just porting of \( \LaTeX \); unnatural specifications/behaviors of \( \LaTeX \) were not adopted.

The followings are major changes from \( \LaTeX \). For more detailed information, see Part III or other sections of this manual.

Command names

\( \LaTeX \) adds several primitives, such as \( \backslash \text{kanjiskip} \), \( \backslash \text{prebreakpenalty} \), and \( \backslash \text{ifydir} \). They can be used as follows:

\begin{verbatim}
\kanjiskip=10pt \dimen0=\kanjiskip
\tbaselineshift=0.1zw
\dimen0=\tbaselineshift
\prebreakpenalty'=100
\ifydir ... \fi
\end{verbatim}

However, we cannot use them under Lua\( \TeX \)-ja. Instead of them, we have to write as the following.

\begin{verbatim}
\ltjsetparameter{kanjiskip=10pt} \dimen0=\ltjgetparameter{kanjiskip}
\ltjsetparameter{tbaselineshift=0.1\zw}
\dimen0=\ltjgetparameter{tbaselineshift}
\ltjsetparameter{prebreakpenalty={`,100}}
\ifnum\ltjgetparameter{direction}=4 ... \fi
\end{verbatim}

Note that \( \LaTeX \) adds new two useful units, namely zw and zh. As shown above, they are changed to \( \zw \) and \( \zh \) respectively in Lua\( \TeX \)-ja.

Linebreak after a Japanese character

In \( \LaTeX \), a line break after Japanese character is ignored (and doesn’t yield a space), since line breaks (in source files) are permitted almost everywhere in Japanese texts. However, Lua\( \TeX \)-ja doesn’t have this feature completely, because of a specification of Lua\( \TeX \). For the detail, see Section 13.

\footnote{Lua\( \TeX \)-ja 20200127.0 introduces \( \ltj@zw \) and \( \ltj@zh \), which are copy of \( \zw \) and \( \zh \).}
Spaces related to Japanese characters  The insertion process of glues/kerns between two Japanese characters and between a Japanese character and other characters (we refer glues/kerns of both kinds as $JAglue$) is rewritten from scratch.

- As LuaTeX’s internal ligature handling is node-based (e.g., \texttt{office} doesn’t prevent ligatures), the insertion process of $JAglue$ is now node-based.
- Furthermore, nodes between two characters which have no effects in line break (e.g., \texttt{special} node) and kerns from italic correction are ignored in the insertion process.
- *Caution: due to above two points, many methods which did for the dividing the process of the insertion of $JAglue$ in $\TeX$ are not effective anymore.* In concrete terms, the following two methods are not effective anymore:
  
  ちょっと ちょっと

  If you want to do so, please put an empty horizontal box (hbox) between it instead:
  ちょっと\hbox{ }

- In the process, two Japanese fonts which only differ in their “real” fonts are identified.

Directions  From version 20150420.0, LuaTeX-ja supports vertical writing. We implement this feature by using callbacks of LuaTeX; so it must not be confused with $\Omega$-style direction support of LuaTeX itself. Due to implementation, the dimension returned by \texttt{\wd}, \texttt{\ht}, or \texttt{\dp} depends on the content of the register only. This is major difference with $\TeX$.

\texttt{\discretionary}  Japanese characters in discretionary break (\texttt{\discretionary}) is not supported.

Greek and Cyrillic letters, and ISO 8859-1 symbols  By default, LuaTeX-ja uses Japanese fonts to typeset Greek and Cyrillic letters. To change this behavior, put \texttt{\ltjsetparameter{\jacharrange={-2,-3}}} in the preamble. For the detailed description, see Subsection 4.1.

  From version 20150906.0, characters which belongs both ISO 8859-1 and JIS X 0208, such as ¶ and §, are now typeset in alphabetic fonts.

1.3 Notations

In this document, the following terms and notations are used:

- Characters are classified into following two types. Note that the classification can be customized by a user (see Subsection 4.1).
  - $JAchar$: standing for characters which is used in Japanese typesetting, such as Hiragana, Katakana, Kanji, and other Japanese punctuation marks.
  - $ALchar$: standing for all other characters like latin alphabets.

We say *alphabetic fonts* for fonts used in $ALchar$, and *Japanese fonts* for fonts used in $JAchar$.

- A word in a sans-serif font with underline (like \texttt{prebreakpenalty}) means an internal parameter for Japanese typesetting, and it is used as a key in \texttt{\ltjsetparameter} command.

- A word in a sens-serif font without underline (like \texttt{fontspec}) means a package or a class of $\TeX$.

- In this document, natural numbers start from zero. $\omega$ denotes the set of all natural numbers which can be used in $\TeX$.

- Kazuki MAEDA
- Noriyuki ABE
- Shuzaburo SAITO
- Takayuki YATO
- Munehiro YAMAMOTO
- MA Qiyuan
2 Getting Started

2.1 Installation

The following packages are needed for the LuaTEX-ja package.

- **LuaTEX** 1.10.0 (or later)
- recent *luaotfload* (v3.1 or later recommended)
- *adobemapping* (Adobe cmap and pdfmapping files)
- *EBTX* 2020-02-02 patch level 5 or later (if you want to use LuaTEX-ja with *EBTX* 2e)
- *etoolbox, everysel* (if you want to use LuaTEX-ja with *EBTX* 2e)
- *ltxcmds, pdftexcmds, filehook, atbegshi*
- *fontspec* v2.7c (or later)
- *Harano Aji fonts* ([https://github.com/trueroad/HaranoAjiFonts](https://github.com/trueroad/HaranoAjiFonts))

More specifically, *HaranoAjiMincho-Regular* and *HaranoAjiGothic-Medium*.

Now LuaTEX-ja is available from CTAN (in the `macros/luatex/generic/luatexja` directory), and the following distributions:

- *TEX Live* (in `texmf-dist/tex/luatex/luatexja`)
- *W32TEX* (in `luatexja.tar.xz`)
- *MiKTeX* (in `luatexja.tar.lzma`); see the next subsection

Harano Aji fonts are available in TeX Live and MiKTeX.

■ HarfBuzz and LuaTEX-ja  Using LuaTEX-ja with LuaHBTEx (LuaTEX integrated with HarfBuzz) is not well tested. Maybe documents can typeset without an error, but with unwanted results (especially, vertical typesetting and \CID).

Especially, *We don’t recommend defining a Japanese font with HarfBuzz*, by specifying `Renderer=Harfbuzz` etc. (*fontspec* or mode=harf (otherwise)).

■ Manual installation

1. Download the source, by one of the following method. At the present, LuaTEX-ja has no stable release.

   - Clone the Git repository by
     ```
     $ git clone git://git.osdn.jp/gitroot/luatex-ja/luatexja.git
     ```

   - Download the tar.gz archive of HEAD in the master branch from
     ```
     http://git.osdn.jp/view?p=luatex-ja/luatexja.git;a=snapshot;h=HEAD;sf=tgz.
     ```

   Note that the master branch, and hence the archive in CTAN, are not updated frequently; the forefront of development is not the master branch.

2. Extract the archive. You will see src/ and several other sub-directories. But only the contents in src/ are needed to work LuaTEX-ja.

3. If you downloaded this package from CTAN, you have to run following commands to generate classes and ltxj-kinsoku.lua (the file which stores default ‘kinsoku’ parameters):
$ cd src
$ lualatex ltjclasses.ins
$ lualatex ltjsclasses.ins
$ lualatex ltjltjdoc.ins
$ luatex ltj-kinsoku_make.tex

Do not forget processing ltj-kinsoku_make.tex.*.{dtx,ins} and ltj-kinsoku_make.tex used here are not needed in regular use.

4. Copy all the contents of src/ into one of your TEXMF tree. TEXMF/tex/luatex/luatexja/ is an example location. If you cloned entire Git repository, making a symbolic link of src/ instead copying is also good.

5. If \texttt{mktexlsr} is needed to update the file name database, make it so.

2.2 Cautions

For changes from \texttt{p\TeX}, see Subsection 1.2.

- The encoding of your source file must be UTF-8. Other encodings, such as EUC-JP or Shift-JIS, are not supported.

- \texttt{Lua\TeX-ja} is very slower than \texttt{p\TeX}, and uses a lot of memory.

- \textbf{(Outdated) note for MiK\TeX\ users} \texttt{Lua\TeX-ja} requires that several CMap files\footnote{UniJIS2004-UTF32-{H,V} and Adobe-Japan1-UCS2.} must be found from \texttt{Lua\TeX}. Strictly speaking, those CMaps are needed only in the first run of \texttt{Lua\TeX-ja} after installing or updating. But it seems that \texttt{MiK\TeX} does not satisfy this condition, so you will encounter an error like the following:

```
! LuaTeX error ...iles (x86)/MiKTeX 2.9/tex/luatex/luatexja/ltj-rmlgbm.lua
bad argument #1 to 'open' (string expected, got nil)
```

If so, please execute a batch file which is written on the Project Wiki (English). This batch file creates a temporary directory, copy CMaps in it, run a test file which loads \texttt{Lua\TeX-ja} in this directory, and finally delete the temporary directory.

- Note that when \texttt{Lua\TeX-ja} is loaded in plain \texttt{\TeX}, we cannot use color specification on font loading, such as

```
\font\hoge=lmroman10-regular.otf:color=FF0000 % \font \texttt{primitive}
```

This is because codes for shifting baseline in math mode (\texttt{Lua\TeX-ja}) collide with and prevents loading codes for font color (\texttt{luaotfload}) in these environments. \textit{We recommend to use \texttt{\TeX} 2020-02-02 (or later)}, since we can avoid this collision in there.

2.3 Using in plain \texttt{\TeX}

To use \texttt{Lua\TeX-ja} in plain \texttt{\TeX}, simply put the following at the beginning of the document:

\texttt{\input luatexja.sty}

This does minimal settings (like \texttt{ptex.tex}) for typesetting Japanese documents:

- The following 12 Japanese fonts are preloaded:

<table>
<thead>
<tr>
<th>direction</th>
<th>classification</th>
<th>font name</th>
<th>“10 pt”</th>
<th>“7 pt”</th>
<th>“5 pt”</th>
</tr>
</thead>
<tbody>
<tr>
<td>yoko (horizontal)</td>
<td>mincho gothic</td>
<td>HaranoAjiMincho-Regular</td>
<td>\tentmin</td>
<td>\sevenmin</td>
<td>\fivemin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HaranoAjiGothic-Medium</td>
<td>\tenmin</td>
<td>\sevengt</td>
<td>\fivemin</td>
</tr>
<tr>
<td>tate (vertical)</td>
<td>mincho gothic</td>
<td>HaranoAjiMincho-Regular</td>
<td>\tentmin</td>
<td>\sevenmin</td>
<td>\fivemin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HaranoAjiGothic-Medium</td>
<td>\tenmin</td>
<td>\sevengt</td>
<td>\fivemin</td>
</tr>
</tbody>
</table>
- The “default” Japanese fonts (and JFMs for them) can be modified by defining \@stdmcfont etc. before one inputs luatexja.sty (Subsection 7.3).

- A character in an alphabetic font is generally smaller than a Japanese font in the same size. So actual size specification of these Japanese fonts is in fact smaller than that of alphabetic fonts, namely scaled by 0.962216.

- The amount of glue that are inserted between a JAchar and an ALchar (the parameter xkanjiskip) is set to

\[(0.25 \cdot 0.962216 \cdot 10)^{\text{pt}} = 2.40554 \text{pt}^{\text{pt}} - 1\text{pt}^{\text{pt}}.\]

### 2.4 Using in \LaTeX

Using in \LaTeX is basically same. To set up the minimal environment for Japanese, you only have to load luatexja.sty:

\texttt{\usepackage{luatexja}}

It also does minimal settings (counterparts in \pLaTeX are plfonts.dtx and pldefs.ltx).

- Font encodings for Japanese fonts are JY3 (for horizontal direction) and JT3 (for vertical direction).

- Traditionally, Japanese documents use only two families: mincho (明朝体) and gothic (ゴシック体). mincho is used in the main text, while gothic is used in the headings or for emphasis.

### 2.4.1 classification commands family

<table>
<thead>
<tr>
<th>classification</th>
<th>commands</th>
<th>family</th>
</tr>
</thead>
<tbody>
<tr>
<td>mincho (明朝体)</td>
<td>\textmc{...}</td>
<td>\mcdefault</td>
</tr>
<tr>
<td>gothic (ゴシック体)</td>
<td>\textgt{...}</td>
<td>\gtdefault</td>
</tr>
<tr>
<td>(Japanese counterpart for typewriter font)</td>
<td>--</td>
<td>--</td>
</tr>
</tbody>
</table>

Here \texttt{\jttdefault} specifies the Japanese font family in \texttt{\verb or \verbatim} environment, and its default value is \texttt{\mcdefault} (mincho family). \texttt{\LaTeX-ja} does not define commands to only switch current Japanese font family to \texttt{\jttdefault}.

- By default, the following fonts are used for these two families.

<table>
<thead>
<tr>
<th>classification</th>
<th>family</th>
<th>\texttt{\bfseries}</th>
<th>\texttt{\textbfseries}</th>
<th>scale</th>
</tr>
</thead>
<tbody>
<tr>
<td>mincho (明朝体)</td>
<td>mc</td>
<td>HaranoAjiMincho-Regular</td>
<td>HaranoAjiGothic-Medium</td>
<td>0.962216</td>
</tr>
<tr>
<td>gothic (ゴシック体)</td>
<td>gt</td>
<td>HaranoAjiGothic-Medium</td>
<td>HaranoAjiGothic-Medium</td>
<td>0.962216</td>
</tr>
</tbody>
</table>

- Note that the bold series (series bx or b) in both family are same as the medium series of gothic family. There is no italic nor slanted shape for these mc and gt.

- From version 20181102.0, one can specifies disablejfm option at loading Lua\TeX-ja. This option prevents loading a patch for \LaTeX, which are needed to support Japanese characters in math mode. Without disablejfm option, one can typeset Japanese characters in math mode as $\mathbb{\mathbf{\text{？}}}$ (see Page 11) as before. Japanese characters in math mode are typeset by the font family mc.

- If you use the beamer class with the default font theme (which uses sans serif fonts) and with Lua\TeX-ja, you might want to change default Japanese fonts to the gothic family. The following line changes the default Japanese font family to it:

\texttt{\renewcommand{\kanjifamilydefault}{\gtdefault}}

---

3 When \ltjclasses classes are used, or luatexja-fontspec (or luatexja-preset) is loaded with match option, \ttfamily changes the current Japanese font family to \texttt{\jttdefault}. These classes and packages also redefine \texttt{\jttdefault} to \texttt{\gtdefault} (gothic family).
However, above settings are not sufficient for Japanese-based documents. To typeset Japanese-based documents, you are better to use class files other than article.cls, book.cls, and so on. At the present, Lua\TeX\-ja has the counterparts of jclasses (standard classes in p\LaTeX) and jsclasses (classes by Haruhiko Okumura), namely, ltjclasses and ltjsclasses.

Original jsclasses use \texttt{\textbackslash mag} primitive to set the main document font size. However, Lua\TeX\ does not support \texttt{\textbackslash mag} in PDF output, so ltjsclasses uses the \texttt{nomag*} option by default to set the main font size. If this causes some unexpected behavior, specify \texttt{nomag} option in \texttt{\documentclass}.

\section*{geometry package and classes for vertical writing}
It is well-known that the geometry package produces the following error, when classes for vertical writing is used:

\begin{verbatim}
! Incompatible direction list can't be unboxed.
\@begindvi \unvbox \@begindvibox
\global \let \@begindvi \empty
\end{verbatim}

Now, Lua\TeX\-ja automatically applies the patch \texttt{ltjp-geometry} to the geometry package, when the direction of the document is \texttt{tate} (vertical writing). This patch \texttt{ltjp-geometry} also can be used in p\LaTeX; for the detail, please refer \texttt{ltjp-geometry.pdf} (Japanese).

\section{Changing Fonts}

\subsection{plain \TeX\ and \\LaTeX\ 2\varepsilon}

\textbf{plain \TeX\} To change Japanese fonts in plain \TeX, you must use the command \texttt{\jfont} and \texttt{\tfont}. So please see Subsection 7.1.

\textbf{\\LaTeX\ 2\varepsilon (NFSS2)} For \\LaTeX\ 2\varepsilon, Lua\TeX\-ja adopted most of the font selection system of p\LaTeX\ 2\varepsilon (in \texttt{plfonts.dtx}).

<table>
<thead>
<tr>
<th>\textbf{encoding}</th>
<th>\textbf{family}</th>
<th>\textbf{series}</th>
<th>\textbf{shape}</th>
<th>\textbf{selection}</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textbf{Alphabetic fonts}</td>
<td>\texttt{\romanencoding}</td>
<td>\texttt{\romanfamily}</td>
<td>\texttt{\romanseries}</td>
<td>\texttt{\romanshape}</td>
</tr>
<tr>
<td>\textbf{Japanese fonts}</td>
<td>\texttt{\kanjiencoding}</td>
<td>\texttt{\kanjifamily}</td>
<td>\texttt{\kanjiseries}</td>
<td>\texttt{\kanjishape}</td>
</tr>
<tr>
<td>\textbf{both}</td>
<td>\texttt{\fontencoding}</td>
<td>\texttt{\fontfamily}</td>
<td>\texttt{\fontseries}</td>
<td>\texttt{\fontshape}</td>
</tr>
<tr>
<td>\textbf{auto select}</td>
<td>\texttt{\fontencoding}</td>
<td>\texttt{\fontfamily}</td>
<td>\texttt{\fontseries}</td>
<td>\texttt{\fontshape}</td>
</tr>
</tbody>
</table>

- \texttt{\fontfamily}, \texttt{\fontseries}, and \texttt{\fontshape} try to change attributes of Japanese fonts, as well as those of alphabetic fonts. Of course, \texttt{\selectfont} is needed to select current text fonts.

Note that \texttt{\fontshape} always changes current alphabetic font shape, but it does not change current Japanese font shape if the target shape is unavailable for current Japanese encoding/family/series. For the detail, see Subsection 10.2.

- \texttt{\fontencoding{encoding}} changes the encoding of alphabetic fonts or Japanese fonts depending on the argument. For example, \texttt{\fontencoding{JY3}} changes the encoding of Japanese fonts to JY3, and \texttt{\fontencoding{T1}} changes the encoding of alphabetic fonts to T1. \texttt{\fontfamily} also changes the current Japanese font family, the current alphabetic font family, or both. For the detail, see Subsection 10.2.

- For defining a Japanese font family, use \texttt{\DeclareKanjiFamily} instead of \texttt{\DeclareFontFamily}. (In previous version of Lua\TeX\-ja, using \texttt{\DeclareFontFamily} didn’t cause any problem. But this no longer applies the current version.)

- Defining a Japanese font shape can be done by usual \texttt{\DeclareFontShape}:

\begin{verbatim}
\DeclareFontShape{JY3}{mc}{b}{n}{<-> s*HaranoAjiMincho--Bold:jfm=ujis;-kern}{% 
Harano Aji Mincho Bold
\end{verbatim}

\texttt{ltjarticle.cls}, \texttt{ltjbook.cls}, \texttt{ltjreport.cls}, \texttt{ltjarticle.cls}, \texttt{ltjbook.cls}, \texttt{ltjreport.cls}. The latter \texttt{ltjt*\.cls} are for vertically written Japanese documents.

\texttt{ltjsarticle.cls}, \texttt{ltjsbook.cls}, \texttt{ltjsreport.cls}, \texttt{ltjsreport.cls}, \texttt{ltjskiyou.cls}.

Same effect as the \texttt{B9xcls} classes (by Takayuki Yato) and jsclasses. However, these classes uses only \TeX\ code, but ltjsclasses uses Lua code.
Table 1. Commands of luatexja-fontspec

■ Japanese characters in math mode

Since \LaTeX supports Japanese characters in math mode, there are sources like the following:

1. \( f_{\text{高温}} \) ~\%  \( f_{\text{high temperature}} \).
2. \[ y = (x-1)^2 + 2 \quad \text{よって} \quad y > 0 \]
3. \$5 \in \text{素} : = \{ p \in \mathbb{N} : \text{p is a prime} \}$.

We (the project members of Lua\TeX-ja) think that using Japanese characters in math mode are allowed if and only if these are used as identifiers. In this point of view,

- The lines 1 and 2 above are not correct, since "高温" in above is used as a textual label, and "よって" is used as a conjunction.
- However, the line 3 is correct, since "素" is used as an identifier.

Hence, in our opinion, the above input should be corrected as:

1. \( f_{\text{高温}} \) \( f_{\text{high temperature}} \).
2. \[ y = (x-1)^2 + 2 \quad \text{よって} \quad y > 0 \]
3. \$5 \in \text{素} : = \{ p \in \mathbb{N} : \text{p is a prime} \}$.

We also believe that using Japanese characters as identifiers is rare, hence we don’t describe how to change Japanese fonts in math mode in this chapter. For the method, please see Subsection 7.6.

When Lua\TeX-ja is loaded with \texttt{disablejfam} option, one cannot write Japanese characters in math mode as $\text{素}$. At that case, one have to use $\texttt{mbox}$ (or $\texttt{text}$ in the amsmath package).

### 3.2 luatexja-fontspec package

To use the functionality of the fontspec package to Japanese fonts, it is needed to load the luatexja-fontspec package in the preamble, as follows:

\begin{verbatim}
\usepackage[⟨options⟩]{luatexja-fontspec}
\end{verbatim}

This luatexja-fontspec package automatically loads luatexja and fontspec packages, if needed.

In the luatexja-fontspec package, several commands are defined as counterparts of original commands in the fontspec package (see Table 1):

The package option of luatexja-fontspec are the followings:

match

If this option is specified, usual family-changing commands such as \texttt{\rmfamily}, \texttt{\textrm}, \texttt{\sffamily}, ... also change Japanese font family.

pass=(⟨opts⟩)

(Obsoleted) Specify options ⟨opts⟩ which will be passed to the fontspec package.
Override the ratio of the font size of Japanese fonts to that of alphabetic fonts. The default value is determined as follows:

- The value of `\Cjascale` is used, if this control sequence is already defined.
- It is calculated automatically from the current Japanese font at the loading of the package, if `\Cjascale` is not defined.

`\Cjascale` is defined in `ltjclasses` and `ltjsclasses`.

All other options listed above are simply passed to the `fontspec` package. This means that two lines below are equivalent, for example.

```latex
\usepackage[no-math]{fontspec}\usepackage{luatexja-fontspec}
\usepackage[no-math]{luatexja-fontspec}
```

Note that kerning information in a font is not used (that is, kern feature is set off) by default in these seven (or eight) commands. This is because of the compatibility with previous versions of LuaTeX-ja (see 7.1).

Below is an example of `\jfontspec`.

```latex
1 \jfontspec[CJKShape=NLC]{HaranoAjiMincho-Regular} →辻鯵
2 \jfontspec[CJKShape=JIS1990]{HaranoAjiMincho-Regular} →辻鯵
3 \jfontspec[CJKShape=JIS1978]{HaranoAjiMincho-Regular} →辻鯵
```

### 3.3 Presets of Japanese fonts

With `luatexja-preset` package, one use one of “preset” to simplify Japanese font setting. For details of package options, and those of each presets, please see Subsection 11.6. The following presets are defined:

- `haranoaji`, `hiragino-pro`, `hiragino-pron`, `ipa`, `ipa-hg`, `ipaex`, `ipaex-hg`, `kozuka-pr6`, `kozuka-pr6n`, `kozuka-pro`, `moga-mobo`, `moga-mobo-ex`, `bizud`, `morisawa-pr6n`, `morisawa-pro`, `ms`, `ms-hg`, `noembed`, `noto-otc`, `noto-otf`, `sourcehan`, `sourcehan-jp`, `ume`, `yu-osx`, `yu-win`, `yu-win10`

For example, this document loads `luatexja-preset` package by

```latex
\usepackage[haranoaji]{luatexja-preset}
```

which means that Harano Aji fonts will be used in this document.

### 3.4 CID, UTF, and macros in `japanese-otf` package

Under pLTeX, `japanese-otf` package (developed by Shuzaburo Saito) is used for typesetting characters which is in Adobe-Japan1-6 CID but not in JIS X 0208. Since this package is widely used, LuaTeX-ja supports some of functions in the `japanese-otf` package, as an external package `luatexja-otf`.

```latex
森UTF{9DD7}外と内田UTF{9592}とがUTF{9AD9}島屋に\`
\CID{7652}飾区の\CID{13706}野家，
\CID{1481}城市，葛西駅，\`
高崎と\CID{8705}UTF{FA11}，濱とajMayuHama\`
\aj半角(カタカナ)ajKakko3\ajMaruYobi{2}\
\ajLig{令和}\ajLig{○問}\ajJIS
```

### 4 Changing Internal Parameters

There are many internal parameters in LuaTeX-ja. And due to the behavior of LuaTeX, most of them are not stored as internal register of TeX, but as an original storage system in LuaTeX-ja. Hence, to assign or acquire those parameters, you have to use commands `\ltjsetparameter` and `\ltjgetparameter`.
Table 2. Characters in predefined character range 8.

| \(\text{§ (U+00A7)}\) | Section Sign |
| \(\text{‘ (U+00B0)}\) | Degree sign |
| \(\text{’ (U+00B4)}\) | Spacing acute |
| \(\times (U+00D7)\) | Multiplication sign |

Table 3. Unicode blocks in predefined character range 1.

| \(U+0080\)–\(U+00FF\) | Latin-1 Supplement |
| \(U+0100\)–\(U+017F\) | Latin Extended-A |
| \(U+0180\)–\(U+024F\) | Latin Extended-B |
| \(U+0250\)–\(U+02AF\) | IPA Extensions |
| \(U+02B0\)–\(U+02FF\) | Spacing Modifier Letters |
| \(U+0300\)–\(U+036F\) | Combining Diacritical Marks |
| \(U+1E00\)–\(U+1EFF\) | Latin Extended Additional |

4.1 Range of JAchars

LuaTeX-ja divides the Unicode codespace \(U+0000\)–\(U+10FFFF\) into character ranges, numbered 1 to 217. The grouping can be (globally) customized by \texttt{\textbackslash ltjdefcharrange}. The next line adds whole characters in Supplementary Ideographic Plane and the character “漢” to the character range 100.

\texttt{\textbackslash ltjdefcharrange{100}{"20000-"2FFFF,`漢}}

A character can belong to only one character range. For example, whole SIP belong to the range 4 in the default setting of LuaTeX-ja, and if one executes the above line, then SIP will belong to the range 100 and be removed from the range 4.

The distinction between \texttt{ALchar} and \texttt{JAchar} is performed by character ranges. This can be edited by setting the jacharrange parameter. For example, the code below is just the default setting of LuaTeX-ja, and it sets

- a character which belongs character ranges 1, 4, 5, and 8 is \texttt{ALchar},
- a character which belongs character ranges 2, 3, 6, 7, and 9 is \texttt{JAchar}.

\texttt{\textbackslash ltjsetparameter{jacharrange={-1, +2, +3, -4, -5, +6, +7, -8, +9}}}

The argument to jacharrange parameter is a list of non-zero integer. Negative integer \(\neg n\) in the list means that “each character in the range \(n\) is an \texttt{ALchar}”, and positive integer \(+n\) means that “… is a \texttt{JAchar}”.

Note that characters \(U+0000\)–\(U+007F\) are always treated as an \texttt{ALchar} (this cannot be customized).

■ Default character ranges LuaTeX-ja predefines nine character ranges for convenience. They are determined from the following data:

- Blocks in Unicode 12.0.0.
- The PXbase bundle for upTeX by Takayuki Yato.

Now we describe these nine ranges. The superscript "J" or "A" after the number shows whether each character in the range is treated as \texttt{JAchars} or not by default. These settings are similar to the prefercjk settings defined in PXbase bundle. Any characters equal to or above \(U+0080\) which does not belong to these eight ranges belongs to the character range 217.

Range 8\(^J\) The intersection of the upper half of ISO 8859-1 (Latin-1 Supplement) and JIS X 0208 (a basic character set for Japanese). The character list is indicated in Table 2.

Range 1\(^A\) Latin characters that some of them are included in Adobe-Japan1-7. This range consists of the Unicode ranges indicated in Table 3, except characters in the range 8 above.

Range 2\(^J\) Greek and Cyrillic letters. JIS X 0208 (hence most of Japanese fonts) has some of these characters.
Table 4. Unicode blocks in predefined character range 3.

Range 3 | Miscellaneous symbols. The block list is indicated in Table 4.

Range 9 | The intersection of the "General Punctuation" block (U+2000–U+206F) and Adobe-Japan1-7 character collection. This character range characters in Table 5.

Range 4 | Characters usually not in Japanese fonts. This range consists of almost all Unicode blocks which are not in other predefined ranges. Hence, instead of showing the block list, we put the definition of this range itself.

\ltjdefcharrange{4}{% 
"500--"10FF, "1200--"1DFF, "2440--"245F, "27C0--"28FF, "2A00--"2AFF, 
"2C00--"27EF, "4D00--"4AFF, "A000--"A0FF, "E000--"F8FF, 
"F800--"FE0F, "FE20--"FE2F, "FE70--"FEFF, "10000--"10FFFF, "1B170--"1F0FF, 
"1F300--"1FFFF, ... (characters in "2000--"206F which are not in range 9) 
} % non-Japanese

Range 5 | Surrogates and Supplementary Private Use Areas.

Range 6 | Characters used in Japanese. The block list is indicated in Table 6.

Range 7 | Characters used in CJK languages, but not included in Adobe-Japan1-7. The block list is indicated in Table 7.

Notes on U+0080–U+00FF | You should treat characters in `\texttt{U+0080–U+00FF}` as `\texttt{ALchar}`, when you use traditional 8-bit fonts, such as the marvosym package.
The value of these parameter can be get by \texttt{\textbackslash xkanjiskip={0pt plus 0.4pt minus 0.4pt}}.

4.2 \texttt{\textbackslash xkanjiskip} and \texttt{\textbackslash kanjiskip}

\texttt{\textbackslash xkanjiskip} is divided into the following three categories:

- Glues/kerns specified in JFM. If \texttt{\textbackslash inhibitglue} is issued around a \texttt{\textbackslash JChar}, this glue will not be inserted at the place.

- The default glue which inserted between two \texttt{\textbackslash JChars} (\texttt{\textbackslash kanjiskip}).

- The default glue which inserted between a \texttt{\textbackslash JChar} and an \texttt{\textbackslash LChar} (\texttt{\textbackslash xkanjiskip}).

The value (a skip) of \texttt{\textbackslash kanjiskip} or \texttt{\textbackslash xkanjiskip} can be changed as the following. Note that only their values at the end of a paragraph or a hbox are adopted in the whole paragraph or the whole hbox.

\begin{verbatim}
\textbackslash ltjsetparameter{\textbackslash kanjiskip={0.0pt plus 0.4pt minus 0.4pt},
\textbackslash xkanjiskip={0.25\textbackslash zw plus 0.1pt minus 1pt}}
\end{verbatim}

Here \texttt{\textbackslash zw} is a internal dimension which stores fullwidth of the current Japanese font. This \texttt{\textbackslash zw} can be used as the unit \texttt{\textbackslash zw} in \texttt{\textbackslash hbox}.

The value of these parameter can be get by \texttt{\textbackslash ltjgetparameter}. Note that the result by \texttt{\textbackslash ltjgetparameter} is not the internal quantities, but a string (hence it cannot be prefixed).

\begin{verbatim}
\textbackslash kanjiskip: \textbackslash ltjgetparameter{\textbackslash kanjiskip},
\textbackslash xkanjiskip: \textbackslash ltjgetparameter{\textbackslash xkanjiskip}
\end{verbatim}

It may occur that JFM contains the data of “ideal width of \texttt{\textbackslash kanjiskip}” and/or “ideal width of \texttt{\textbackslash xkanjiskip}”. To use these data from JFM, set the value of \texttt{\textbackslash kanjiskip} or \texttt{\textbackslash xkanjiskip} to \texttt{\textbackslash maxdimen} (these “ideal width” cannot be retrieved by \texttt{\textbackslash ltjgetparameter}).
4.3 Insertion setting of xkanjiskip

It is not desirable that xkanjiskip is inserted into every boundary between JAchars and ALchars. For example, xkanjiskip should not be inserted after opening parenthesis (e.g., compare “(あ)” and “(あ)”). LuaTeX-ja can control whether xkanjiskip can be inserted before/after a character, by changing jaxspmode for JAchars and alxspmode parameters ALchars respectively.

\begin{verbatim}
1 \ltjsetparameter{jaxspmode={`あ,preonly}, alxspmode={`,postonly}}
pあqいu
2 \ltjsetparameter{alxspmode={`あ,preonly}, jaxspmode={`,postonly}}
\end{verbatim}

The second argument preonly means that the insertion of xkanjiskip is allowed before this character, but not after. The other possible values are postonly, allow, and inhibit.

jaxspmode and alxspmode use a same table to store the parameters on the current version. Therefore, line 1 in the code above can be rewritten as follows:

\begin{verbatim}
\ltjsetparameter{alxspmode={`あ,preonly}, jaxspmode={`,postonly}}
\end{verbatim}

One can use also numbers to specify these two parameters (see Subsection 8.1).

If you want to enable/disable all insertions of kanjiskip and xkanjiskip, set autospacing and autoxspacing parameters to true/false, respectively.

4.4 Shifting the baseline

To make a match between a Japanese font and an alphabetic font, sometimes shifting of the baseline of one of the pair is needed. In \TeX{}, this is achieved by setting \texttt{\baselineskip} (or \texttt{\baselineshift}) to a non-zero length (the baseline of ALchar is shifted below). However, for documents whose main language is not Japanese, it is good to shift the baseline of Japanese fonts, but not that of alphabetic fonts. Because of this, Lua\TeX{}-ja can independently set the shifting amount of the baseline of alphabetic fonts and that of Japanese fonts.

<table>
<thead>
<tr>
<th></th>
<th>Horizontal writing (yoko direction) etc.</th>
<th>Vertical writing (tate direction)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alphabetic fonts</td>
<td>yalbaselineshift parameter</td>
<td>talbaselineshift parameter</td>
</tr>
<tr>
<td>Japanese fonts</td>
<td>yjabaselineshift parameter</td>
<td>tjabaselineshift parameter</td>
</tr>
</tbody>
</table>

Here the horizontal line in the below example is the baseline of a line.

\begin{verbatim}
1 \vrule width 150pt height 0.2pt depth 0.2pt \\
2 \hskip-120pt
3 \ltjsetparameter{yjabaselineshift=0pt, yalbaselineshift=0pt}abcあいう
4 \ltjsetparameter{yjabaselineshift=5pt, yalbaselineshift=2pt}abcあいう
\end{verbatim}

There is an interesting side-effect: characters in different size can be vertically aligned center in a line, by setting two parameters appropriately. The following is an example (beware the value is not well tuned):

\begin{verbatim}
1 \vrule width 150pt height 4.17pt depth -4.217pt \\
2 \kern-150pt
3 \large 西北漢字
4 \{\scriptsize
5 \ltjsetparameter{yjabaselineshift=-1.757pt, yalbaselineshift=-1.757pt}
6 西北漢字あいう
7 \}あいうabc
\end{verbatim}

Note that setting positive yalbaselineshift or talbaselineshift parameters does not increase the depth of one-letter syllable p of AlChar, if its left-protrusion (\texttt{\lpcode}) and right-protrusion (\texttt{\rpcode}) are both non-zero. This is because

- These two parameters are implemented by setting yoffset field of a glyph node, and this does not increase the depth of the glyph.
To cope with the above situation, LuaTeX-ja automatically supplies a rule in every syllable.

However, we cannot use this “supplying a rule” method if a syllable comprises just one letter whose $\backslash pcode$ and $\backslash rcode$ are both non-zero.

This problem does not apply for $\text{yjbaselineshift}$ nor $\text{tjbaselineshift}$, because a $\text{JAchar}$ is encapsulated by a horizontal box if needed.

### 4.5 kinsoku parameters and OpenType features

Among parameters which related to Japanese word-wrapping process ($\text{kinsoku shori}$),

$\text{jaxspmode}$, $\text{alxspmode}$, $\text{prebreakpenalty}$, $\text{postbreakpenalty}$ and $\text{kcatcode}$

are stored by each character codes.

OpenType font features are ignored in these parameters. For example, a fullwidth katakana “ア” on line 10 in the below input is replaced to its halfwidth variant “ア”, by hwid feature. However, the penalty inserted after it is 10 which is the $\text{postbreakpenalty}$ of “ア”, not 20.

```latex
\ltjsetparameter{postbreakpenalty={`ア, 10}}
\ltjsetparameter{postbreakpenalty={`7, 20}}
\newcommand\showpostpena[1]{% \leavevmode\setbox0=\hbox{#1\hbox{}}% \unhbox0\setbox0=\lastbox\the\lastpenalty}
\showpostpena{ア}, \showpostpena{ア}, \showpostpena{ア} \{\addjfontfeatures{CharacterWidth=Half}\showpostpena{ア}}
```

Part II

Reference

5 \catcode in Lua\TeX-ja

5.1 Preliminaries: \catcode in \p\TeX and \up\TeX

In \p\TeX and \up\TeX, the value of \catcode determines whether a Japanese character can be used in a control word. For the detail, see Table 8.

\catcode can be set by a row of JIS X 0208 in \p\TeX, and generally by a Unicode block\(^7\) in \up\TeX. So characters which can be used in a control word slightly differ between \p\TeX and \up\TeX.

5.2 Case of Lua\TeX-ja

The role of \catcode in \p\TeX and \up\TeX can be divided into the following four kinds, and Lua\TeX-ja can control these four kinds separately:

- Distinction between \texttt{JAchar} or \texttt{ALchar} is controlled by the character range, see Subsection 4.1.
- Whether the character can be used in a control word is controlled by setting \catcode to 11 (enabled) or 12 (disabled), as usual.
- Whether \texttt{icharwidowpenalty} can be inserted before the character is controlled by the lowermost bit of the \catcode parameter.
- Linebreak after a \texttt{JAchar} does not produce a space.

Default setting of \catcode of Unicode characters are located in \texttt{plain \LaTeX} 1uarex-unicode-letters.tex, which is based on unicode-letters.tex (for X\TeX).

\LaTeX now included in \LaTeX kernel as unicode-letters.def.

However, the default setting of \catcode differs between X\TeX and \LaTeX, by the following reasons:

- (plain format) 1uarex-unicode-letters.tex is based on old unicode-letters.tex.
- The latter half of unicode-letters.tex and unicode-letters.def sets \catcode of several characters to 11, via setting \texttt{XeTeXCharClass}. However, this latter half does not exist (plain case), or not executed (\LaTeX case) in \LaTeX.

In other words,

\texttt{plain \LaTeX} Kanji nor kana characters cannot be used in a control word, in the default setting of plain \LaTeX.

\texttt{Lua\LaTeX} In recent (2015-10-01 or later) Lua\LaTeX, Kanji and kana characters in a control word is supported (these catcode are 11), but not fullwidth alphanumeric and several other characters.

This would be inconvenient for \p\TeX users to shifting to Lua\TeX-ja, since several control words containing Kanji or other fullwidth characters, such as \texttt{西暦} or \texttt{1 年目} are used in \p\TeX. Hence, Lua\TeX-ja have a counterpart of unicode-letters.tex for Lua\TeX, to match the \catcode setting with that of X\TeX.

5.3 Non-kanji characters in a control word

Because the engine differ, so non-kanji JIS X 0208 characters which can be used in a control word differ in \p\TeX, in \up\TeX, and in Lua\TeX-ja. Table 9 shows the difference. Except for four characters “・”, “゛”, “゜”, “゠”, Lua\TeX-ja admits more characters in a control word than \up\TeX.

Difference becomes larger, if we consider non-kanji JIS X 0213 characters. For the detail, see https://github.com/h-kitagawa/kct.

\(^7\) \up\TeX divides U+FF00–U+FFEF (Halfwidth and Fullwidth Forms) into three subblocks, and \catcode can be set by a subblock.

6 Directions

Lua\TeX{} supports four \Omega-style directions: TLT, TRT, RTT and LTL. However, neither directions are not well-suited for typesetting Japanese vertically, hence we implemented vertical writing by rotating TLT-box by 90 degrees.

Lua\TeX{}-ja supports four directions, as shown in Table 10. The second column (yoko direction) is just horizontal writing, and the third column (tate direction) is vertical writing. The fourth column (dtou direction) is actually a hidden feature of p\TeX{}. We implemented this for debugging purpose. The fifth column (utod direction) corresponds the “tate (math) direction” of p\TeX{}.

Directions can be changed by \texttt{\yoko}, \texttt{\tate}, \texttt{\dtou}, \texttt{\utod}, only when the current list is null. These commands cannot be executed in unrestricted horizontal modes, nor math modes. The direction of a math formula is changed to \texttt{\utod}, when the direction outside the math formula is \texttt{\tate} (vertical writing).

6.1 Boxes in different direction

As in p\TeX{}, one can use boxes of different direction in one document. The below is an example.
Table 10. Directions supported by LuaTEX-ja

<table>
<thead>
<tr>
<th>Commands</th>
<th>horizontal (yoko direction)</th>
<th>vertical (tate direction)</th>
<th>dtou direction</th>
<th>utod direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beginning of the page</td>
<td>yoko</td>
<td>tate</td>

<td>Right</td>
</tr>
<tr>
<td>Beginning of the line</td>
<td>Left</td>
<td>Top</td>
<td>Bottom</td>
<td>Top</td>
</tr>
<tr>
<td>Used Japanese font</td>
<td>horizontal (\jfont)</td>
<td>vertical (\tfont)</td>
<td>horizontal (90° rotated)</td>
<td></td>
</tr>
</tbody>
</table>

Example

```
\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{example.png}
\caption{Example}
\end{figure}
```

(Notation used in Ω)

TLT  RTR, RTT  LBL  RTR

Table 11 shows how a box is arranged when the direction inside the box and that outside the box differ.

\section*{\texttt{\wd} and direction} In \LaTeX, \texttt{\wd}, \texttt{\ht}, \texttt{\dp} means the dimensions of a box register \textit{with respect to the current direction}. This means that the value of \texttt{\wd8} etc. might differ when the current direction is different, even if \texttt{\box8} stores the same box. However, this no longer applies in LuaTEX-ja.

```
\begin{verbatim}
\setbox0=\hbox to 20pt{foo}
\the\wd0, \hbox{\tate\vrule\the\wd0}
\wd0=100pt
\the\wd0, \hbox{\tate \the\wd0}
\end{verbatim}
```

To access box dimensions \textit{with respect to current direction}, one have to use the following commands instead of \texttt{\wd} wtc.

\begin{verbatim}
\ltjgetwd(num), \ltjgetht(num), \ltjgetdp(num)
\end{verbatim}

These commands return an \textit{internal dimension} of \texttt{\box(num)} with respect to the current direction. One can use these in \texttt{\dimexpr} primitive, as the followings.

```
\dimexpr 2*\ltjgetwd42-3pt\relax, \the\ltjgetwd1701
```

The following is an example.

```
\begin{verbatim}
\parindent0pt
\setbox32767=\hbox{\yokoよこぐみ}
\fboxsep=0mm\fbox{\copy32767}
\vbox{\hsize=20mm\raggedleft \yoko YOKO \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\vbox{\hsize=20mm\raggedleft \tate TATE \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\vbox{\hsize=20mm\raggedleft \dtou DTOU \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\end{verbatim}
```

20
Table 11. Boxes in different direction

<table>
<thead>
<tr>
<th>typeset in yoko direction</th>
<th>typeset in tate or utod direction</th>
<th>typeset in dtou direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>$W_y = h_y + d_y$</td>
<td>$W_T = h_T + d_T$</td>
<td>$W_D = h_D + d_D$</td>
</tr>
<tr>
<td>$H_T = w_y$</td>
<td>$H_T = w_y/2$</td>
<td>$H_D = w_y$</td>
</tr>
<tr>
<td>$D_T = 0$ pt</td>
<td>$D_T = w_D/2$</td>
<td>$D_D = h_D$</td>
</tr>
</tbody>
</table>

\[
\texttt{\textbackslash ltjsetwd}\langle\text{num}\rangle=\langle\text{dimen}\rangle, \texttt{\textbackslash ltjsetht}\langle\text{num}\rangle=\langle\text{dimen}\rangle, \texttt{\textbackslash ltjsetdp}\langle\text{num}\rangle=\langle\text{dimen}\rangle
\]

These commands set the dimension of \texttt{\textbackslash box}\langle\text{num}\rangle. One does not need to group the argument \langle\text{num}\rangle; four calls of \texttt{\textbackslash ltjsetwd} below have the same meaning.

\texttt{\textbackslash ltjsetwd}42 \texttt{\textbackslash 20pt}, \texttt{\textbackslash ltjsetwd}42=\texttt{\textbackslash 20pt}, \texttt{\textbackslash ltjsetwd}42=\texttt{\textbackslash 20pt}, \texttt{\textbackslash ltjsetwd}42=\texttt{\textbackslash 20pt}

### 6.2 Getting current direction

The \texttt{\textbackslash direction} parameter returns the current direction, and the \texttt{\textbackslash boxdir} parameter (with the argument \langle\text{num}\rangle) returns the direction of a box register \texttt{\textbackslash box}\langle\text{num}\rangle. The returned value of these parameters are a \textit{string}:

<table>
<thead>
<tr>
<th>Direction</th>
<th>yoko</th>
<th>tate</th>
<th>dtou</th>
<th>utod</th>
<th>(empty)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned value</td>
<td>4</td>
<td>3</td>
<td>1</td>
<td>11</td>
<td>0</td>
</tr>
</tbody>
</table>

\begin{verbatim}
1 \texttt{\leavevmode}\textbackslash def\textbackslash DIR{\textbackslash ltjgetparameter{direction}}
2 \texttt{\textbackslash hbox{\textbackslash yoko \DIR}, \texttt{\textbackslash hbox{\textbackslash tate\DIR}},}
3 \texttt{\textbackslash hbox{\textbackslash dtou\DIR}, \texttt{\textbackslash hbox{\textbackslash utod}\DIR}},
4 \texttt{\textbackslash hbox{\textbackslash tate$\texttt{\textbackslash hbox{\textbackslash tate math: \DIR}$}}
5 \texttt{\setbox2=\texttt{\textbackslash hbox{\textbackslash tate}}\texttt{\ltjgetparameter{boxdir}}\{2}
\end{verbatim}
6.3 Overridden box primitives

To cope with multiple directions, the following primitives are overridden by Lua\TeX-ja, using `\protected\def`.

\begin{verbatim}
\unhbox\langle num \rangle, \unvbox\langle num \rangle, \unhcopy\langle num \rangle, \unvcopy\langle num \rangle
\vadjust{\langle material \rangle}
\insert\langle number \rangle{\langle material \rangle}
\lastbox
\raise\langle dimen\rangle\langle box \rangle, \lower\langle dimen\rangle\langle box \rangle etc., \vcenter
\vcenter
\end{verbatim}

7 Font Metric and Japanese Font

7.1 \jfont

To load a font as a Japanese font (for horizontal direction), you must use the `\jfont` instead of `\font`, while `\jfont` admits the same syntax used in `\font`. Lua\TeX-ja automatically loads \luaotfload package, so TrueType/OpenType fonts with features can be used for Japanese fonts:

\begin{verbatim}
\jfont\tradmc={IPAexMincho:script=latn;+trad;-kern;jfm=ujis} at 14pt
\end{verbatim}

\begin{verbatim}
\begin{verbatim}
\tradmc 当／体／医／区
\end{verbatim}
\end{verbatim}

Note that the defined control sequence (`\tradmc` in the example above) using `\jfont` is not a `font_def` token, but a macro. Hence the input like `\fontname\tradmc` causes an error. We denote control sequences which are defined in `\jfont` by `⟨jfont_cs⟩`.

\section*{JFM}

A JFM has measurements of characters and glues/kerns that are automatically inserted for Japanese typesetting. The structure of JFM will be described in the next subsection. At the calling of `\jfont`, you must specify which JFM will be used for this font by the following keys:

\begin{verbatim}
\jfm=⟨name⟩
\end{verbatim}

Specify the name of (horizontal) JFM. If specified JFM has not been loaded, Lua\TeX-ja search and load a file named `jfm-⟨name⟩.lua`.

The following horizontal JFMs are shipped with Lua\TeX-ja:

\begin{verbatim}
jfm-ujis.lua A standard horizontal JFM in Lua\TeX-ja. This JFM is based on `upnmlminr-h.tfm`, a metric for UTF/OTF package that is used in up\TeX. When you are going to use the luatexja-otf package, you should use this JFM.
\end{verbatim}
Figure 1. Example of jfmvar key

\begin{multicols}{2}
\begin{itemize}
\item \texttt{\newcommand\test{\vrule ダイナミックダイクマ\vrule}}
\item \texttt{\jfont\KMFW = HaranoAjiMincho-Regular:jfm=prop;\jfont\KMFK = HaranoAjiMincho-Regular:jfm=prop at 17.28pt \jfont\KMPW = HaranoAjiMincho-Regular:jfm=prop;script=dflt;+palt;\jfont\KMPK = HaranoAjiMincho-Regular:jfm=prop;script=dflt;+palt;+kern at 17.28pt}
\item \texttt{\begin{multicols}{2}}
\item \texttt{\ltjsetparameter\{kanjiskip=0pt\}}
\item \texttt{\KMFW\test \KMFK\test \KMPW\test \KMPK\test}
\item \texttt{\ltjsetparameter\{kanjiskip=3pt\}}
\item \texttt{\KMFW\test \KMFK\test \KMPW\test \KMPK\test}
\item \texttt{\end{multicols}}
\end{itemize}
\end{multicols}

Figure 2. Kerning information and kanjiskip

\texttt{jfm-jis.lua} A counterpart for \texttt{jis.tfm}, "JIS font metric" which is widely used in p\TeX. A major difference between \texttt{jfm-ujis.lua} and this \texttt{jfm-jis.lua} is that most characters under \texttt{jfm-ujis.lua} are square-shaped, while that under \texttt{jfm-jis.lua} are horizontal rectangles.

\texttt{jfm-min.lua} A counterpart for \texttt{min10.tfm}, which is one of the default Japanese font metric shipped with p\TeX.

The difference among these three JFMs is shown in Table 12.

Furthermore, Lua\TeX-ja also ship two JFMs, namely \texttt{jfm-prop.lua} and \texttt{jfm-propw.lua}, for "proportional typesetting". Both JFMs don't have any character width information, nor glues/kerns information. \texttt{jfm-prop.lua} also also not have character height and depth information, while \texttt{jfm-propw.lua} has them.

\texttt{jfmvar=(string)}

Sometimes there is a need that ....

\textbf{Using kerning information in a font} Some fonts have information for inter-glyph spacing. Lua\TeX-ja 20140324.0 or later treats kerning spaces like an italic correction; any glue and/or kern from the JFM and a kerning space can coexist. See Figure 2 for detail.

Note that in \texttt{\setmainjfont} etc. which are provided by luatexja-fontspec package, kerning option is set off (\texttt{\Kerning=Off}) by default, because of the compatibility with previous versions of Lua\TeX-ja.
\[ \text{extend and slant } \] The following setting can be specified as OpenType font features:

\begin{itemize}
\item \texttt{extend=⟨extend⟩} expand the font horizontally by ⟨extend⟩.
\item \texttt{slant=⟨slant⟩} slant the font.
\end{itemize}

Note that Lua\TeX-ja doesn’t adjust JFMs by these \texttt{extend} and \texttt{slant} settings; one have to write new JFMs on purpose. For example, the following example uses the standard JFM \texttt{jfm-ujis.lua}, hence letter-spacing and the width of italic correction are not correct:

\begin{verbatim}
\font\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis\-kern
\font\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis\-kern
\Eあいうえお
\Sあいう/
\end{verbatim}

\[ \text{ltjksp} \]

\texttt{kanjiskip\_natural}, \texttt{kanjiskip\_stretch}, \texttt{kanjiskip\_shrink} keys (Page ??) makes that Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}. This functionality is disabled by \texttt{-ltjksp} specification, as shown in Figure 3.

7.2 \texttt{tfont}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax used in \texttt{font} and \texttt{jfont}. A font defined by \texttt{tfont} differs from that by \texttt{jfont} differs the following points from that by \texttt{jfont}:

\begin{itemize}
\item OpenType Feature \texttt{vrt2}\textsuperscript{8} is automatically activated, unless \texttt{vert} and/or \texttt{vrt2} are explicitly activated or deactivated (as the second line in the example below).
\begin{verbatim}
\fnt\S=HaranoAjiMincho-Regular:jfm=ujisv\% vrt2 is automatically activated
\fnt\T=HaranoAjiMincho-Regular:jfm=ujisv\% vert and vrt2 are not activated
\fnt\U=file:ipaexm.ttf:jfm=ujisv
\hspace{\textwidth}
\% vert is automatically activated, since this font does not have vrt2
\end{verbatim}
\item Sometimes \texttt{vert} and/or \texttt{vrt2} are not activated while one specified activation of these feature. This is because the font does not define these features in current combination of script tag and language system identifier.
In this situation, Lua\TeX-ja performs all replacements which is defined in \texttt{vert} feature for some scripts for some languages.
\item Furthermore, a glyph is automatically rotated 90 degrees, if it is not replaced by \texttt{vert} feature for \texttt{any} script for \texttt{any} language, and if it is marked as ’r’ or ”Tr” in UAX \#50.
\item One have to specify the name of vertical JFM in \texttt{jfm=⟨name⟩}. Lua\TeX-ja ships following vertical JFMs:
\begin{itemize}
\item \texttt{jfm-ujisv.lua} A standard vertical JFM in Lua\TeX-ja. This JFM is based on \texttt{upnmlminr-v.tfm}, a metric for UTF/OTF package that is used in up\TeX.
\item \texttt{jfm-tmin.lua} A counterpart for \texttt{tmin10.tfm}, which is one of the default Japanese font metric shipped with p\TeX.
\end{itemize}
\end{itemize}

\[ \text{If the font does not define vrt2 feature, vert is used instead.}\]
• If vert and/or vrt2 features are activated, one can specify jpotf to additional substitutions. By default, it substitutes ideographic comma/period for fullwidth comma/period, and double prime quotation marks for double quotation marks (See Figure 4). One can customize substitutions by lua function luatexja.jfont.register_vert_replace (see Japanese version of this manual).

7.3 Default Japanese fonts and JFMs

If following commands are defined at loading LuaTeX-ja package, these change default Japanese fonts and JFMs for them:

\ltj@stdmcfont The default Japanese font for the mincho family.
\ltj@stdgtfont The default Japanese font for the gothic family.
\ltj@stdyokojfm The default JFM for horizontal direction.
\ltj@stdtatejfm The default JFM for vertical direction.

For example,
\def\ltj@stdmcfont{IPAMincho}
\def\ltj@stdgtfont{IPA Gothic}

makes that IPA Mincho and IPA Gothic will be used as default Japanese fonts, instead of Harano Aji fonts. This feature is intended for classes which use special JFMs. It is recommended to use luatexja-preset or luatexja-fontspec package to select standard fonts in ordinary \LaTeX sources.

For compatibility with earlier versions, LuaTeX-ja reads luatexja.cfg automatically if it is found by LuaTeX. One should not overuse this luatexja.cfg; it will overwrite the definition of \ltj@stdmcfont and others.

7.4 Prefix psft

Besides “file” and “name” prefixes which are introduced in the luaotfload package, LuaTeX-ja adds “psft” prefix in \jfont (and \font), to specify a “name-only” Japanese font which will not be embedded to PDF. Note that these non-embedded fonts under current LuaTeX has Identity-H encoding, and this violates the standard ISO32000-1:2008 ([10]).

OpenType font features, such as “+jp90”, have no meaning in name-only fonts using “psft” prefix, because we can’t expect what fonts are actually used by the PDF reader. Note that extend and slant settings (see above) are supported with psft prefix, because they are only simple linear transformations.

---

9This is because commands has @ in their names.
The default font defined by using `psft` prefix is for Japanese typesetting; it is Adobe-Japan1-7 CID-keyed font. One can specify `cid` key to use other CID-keyed non-embedded fonts for Chinese or Korean typesetting.

```latex
\jfont\testJ={psft:Ryumin-Light:cid=Adobe-Japan1-7;jfm=jis} % Japanese
\jfont\testD={psft:Ryumin-Light:jfm=jis} % default: Adobe-Japan1-7
\jfont\testC={psft:AdobeMingStd-Light:cid=Adobe-CNS1-7;jfm=jis}% Traditional Chinese
\jfont\testG={psft:SimSun:cid=Adobe-GB1-5;jfm=jis} % Simplified Chinese
\jfont\testK={psft:Batang:cid=Adobe-Korea1-2;jfm=jis} % Korean
\jfont\testKR={psft:SourceHanSerifAKR9:cid=Adobe-KR-9;jfm=jis}% Korean
```

Note that the code above specifies `jfm-jis.lua`, which is for Japanese fonts, as JFM for Chinese and Korean fonts.

At present, Lua\TeX-ja supports only 5 values written in the sample code above. Specifying other values, e.g.,

```latex
\jfont\test={psft:Ryumin-Light:cid=Adobe-Japan2;jfm=jis}
```

produces the following error:

```latex
! Package luatexja Error: bad cid key `Adobe-Japan2'.
See the luatexja package documentation for explanation.
Type \<return> for immediate help.
<to be read again>
\par
\l.78
```

I couldn't find any non-embedded font information for the CID `Adobe-Japan2`. For now, I'll use `Adobe-Japan1-6'.

Please contact the LuaTeX-ja project team.

```
?
```

### 7.5 Structure of a JFM file

A JFM file is a Lua script which has only one function call:

```latex
luatexja.jfont.define_jfm { ... }
```

Real data are stored in the table which indicated above by `{ ... }`. So, the rest of this subsection are devoted to describe the structure of this table. Note that all lengths in a JFM file are floating-point numbers in design-size unit.

- `version=(version)` (optional, default value is 1)
  - The version JFM. Currently 1, 2, and, 3 are supported
- `dir=(direction)` (required)
  - The direction of JFM. 'yoko' (horizontal) or 'tate' (vertical) are supported.
- `zw=(length)` (required)
  - The amount of the length of the "full-width".
- `zh=(length)` (required)
  - The amount of the "full-height" (height + depth).
- `kanjiskip={⟨natural⟩, ⟨stretch⟩, ⟨shrink⟩}` (optional)
  - This field specifies the "ideal" amount of kanjiskip. As noted in Subsection 4.2, if the parameter `kanjiskip` is `\maxdimen`, the value specified in this field is actually used (if this field is not specified in JFM, it is regarded as 0 pt). Note that ⟨stretch⟩ and ⟨shrink⟩ fields are in design-size unit too.
- `xkanjiskip={⟨natural⟩, ⟨stretch⟩, ⟨shrink⟩}` (optional)
  - Like the kanjiskip field, this field specifies the "ideal" amount of `xkanjiskip`. 26
Consider a Japanese character node which belongs to a character class whose the align field is 'middle'.

- The black rectangle is the imaginary body of the node. Its width, height, and depth are specified by JFM.
- Since the align field is 'middle', the "real" glyph is centered horizontally (the green rectangle) first.
- Furthermore, the glyph is shifted according to values of fields left and down. The ultimate position of the real glyph is indicated by the red rectangle.

Figure 5. The position of the real glyph (horizontal Japanese fonts)

Character classes  Besides from above fields, a JFM file have several sub-tables those indices are natural numbers. The table indexed by \( i \in \omega \) stores information of character class \( i \). At least, the character class 0 is always present, so each JFM file must have a sub-table whose index is [0]. Each sub-table (its numerical index is denoted by \( i \)) has the following fields:

- **chars\(=\{(\text{character}), \ldots\}\) (required except character class 0)**
  This field is a list of characters which are in this character type \( i \). This field is optional if \( i = 0 \), since all JAchar which do not belong any character classes other than 0 are in the character class 0 (hence, the character class 0 contains most of JAchars). In the list, character(s) can be specified in the following form:
  - a Unicode code point
  - the character itself (as a Lua string, like ‘あ’)
  - a string like ‘あ*’ (the character followed by an asterisk)
  - several "imaginary" characters (We will describe these later.)

- **width=⟨length⟩, height=⟨length⟩, depth=⟨length⟩, italic=⟨length⟩ (required)**
  Specify the width of characters in character class \( i \), the height, the depth and the amount of italic correction. All characters in character class \( i \) are regarded that its width, height, and depth are as values of these fields. The default values are shown in Table 13.

- **left=⟨length⟩, down=⟨length⟩, align=⟨align⟩**
  These fields are for adjusting the position of the "real" glyph. Legal values of align field are 'left', 'middle', and 'right'. If one of these 3 fields are omitted, left and down are treated as 0, and align field is treated as 'left'. The effects of these 3 fields are indicated in Figure 5 and Figure 6.
  In most cases, left and down fields are 0, while it is not uncommon that the align field is 'middle' or 'right'. For example, setting the align field to 'right' is practically needed when the current character class is the class for opening delimiters'.

- **kern={\[\;]=⟨kern⟩, \[\;′]=⟨kern⟩, \[ratio=⟨ratio⟩]\}, \ldots\}**
  Specifies the amount of kern or glue which will be inserted between characters in character class \( i \) and those in character class \( j \).

<table>

<td>0.0</td>
</tr>
</tbody>
</table>

Table 13. Default values of width field and other fields
Figure 6. The position of the real glyph (vertical Japanese fonts)

⟨ratio⟩ specifies how much the glue is originated in the “right” character. It is a real number between 0 and 1, and treated as 0.5 if omitted. For example, the width of a glue between an ideographic full stop “。” and a fullwidth middle dot “・” is three-fourth of fullwidth, namely halfwidth from the ideographic full stop, and quarter-width from the fullwidth middle dot. In this case, we specify ⟨ratio⟩ to \(\frac{0.25}{0.5 + 0.25} = \frac{1}{3}\).

In case of glue, one can specify following additional keys in each \(\mathcal{J}\) subtable:

- **priority=⟨priority⟩** An integer in \([-4, 3]\) (treated as 0 if omitted), or a pair of these integers \{(stretch), (shrink)\} (version 2 or later). This is used only in line adjustment with priority by luatexja-adjust (see Subsection 11.3). Higher value means the glue is easy to stretch, and is also easy to shrink.

- **kanjiskip**
  - **natural=⟨num⟩, kanjiskip_stretch=⟨num⟩, kanjiskip_shrink=⟨num⟩**
    These keys specifies the amount of the natural width of kanjiskip (the stretch/shrink part, respectively) which will be inserted in addition to the original JFM glue. Default values of them are all 0.

As an example, in jfm-ujis.lua, the standard JFM in horizontal writing, we have

- Between an ordinal letter “あ” and an ideographic opening bracket, we have a glue whose natural part and shrink part are both half-width, while its stretch part is zero. However, this glue also can be stretched as much as the stretch part of kanjiskip times the value of kanjiskip_stretch key (1 in this case).
- Between an ideographic closing brackets (the ideographic comma “，” is included) and an ordinal letter, we have the same glue. Again, this glue also can be stretched as much as the stretch part of kanjiskip times the value of kanjiskip_stretch key (1 in this case).
- Between an ideographic opening bracket and an ordinal letter and between an ordinal letter and an ideographic closing bracket, we have a glue whose natural part and stretch part are both zero, while its shrink part as much as the shrink part of kanjiskip.

Hence we have the following result:

```latex
\leavevmode
\ltjsetparameter{kanjiskip=0pt plus 3\zw}
\vrule\hbox to 15\zw{あ「い」う,えお}\vrule
\vrule\hbox{あ「い」う,えお}\vrule\par
\ltjsetparameter{kanjiskip=0pt minus \zw}
\vrule\hbox to 6.5\zw{あ「い」う,えお}\vrule
```

**end_stretch=⟨kern⟩, end_shrink=⟨kern⟩** (optional, version 1 only)

**end_adjust=\{(⟨kern⟩, ⟨kern⟩, ...\}** (optional, version 2 or later)

**round_threshold=⟨float⟩** (optional, version 3 or later, only available in character class 0)
Character to character classes  We explain how the character class of a character is determined, using jfm-test.lua which contains the following:

```lua
[8] = {
    chars = { '漢' },
    align = 'left', left = 0.0, down = 0.0,
    width = 1.0, height = 0.88, depth = 0.12, italic=0.0,
},
[2000] = {
    chars = { '。', 'ヒ' },
    align = 'left', left = 0.0, down = 0.0,
    width = 0.5, height = 0.88, depth = 0.12, italic=0.0,
},
```

Now consider the following input/output:

```
\jfont\a=IPAexMincho:jfm=test;+hwid
\setbox0\hbox{\a \ヒ 漢}
\the\wd0 15.0pt
```

Now we look why the above source outputs 15 pt.

1. The character "ヒ" is converted to its half width form "ヒ" by hwid feature.
2. According to the JFM, the character class of "ヒ" is 2000, hence its width is halfwidth.
3. The character class of "漢" is zero, hence its width is fullwidth.
4. Hence the width of \hbox equals to 15 pt.

This example shows that the character class of a character is generally determined after applying font features by luaotfload.

However, if the class determined by the glyph after application of features is zero, LuaTeX-ja adopts the class determined by the glyph before application of features. The following input is an example.

```
\jfont\a=HaranoAjiMincho-Regular:jfm=test;+vert
\a 漢。
\inhibitglue 漢 漢
```

Here, the character class of the ideographic full stop "。" (U+3002) is determined as follows:

1. As the case of "ヒ", the ideographic full stop "。" is converted to its vertical form " 。" (U+FE12) by vert feature.
2. The character class of " 。", according to the JFM is zero.
3. However, LuaTeX-ja remembers that this " 。" is obtained from " 。" by font features. The character class of " 。" is non-zero value, namely, 2000.
4. Hence the ideographic full stop " 。" in above belongs the character class 2000.

Imaginary characters  As described before, one can specify several “imaginary characters” in chars field. The most of these characters are regarded as the characters of class 0 in \TeX. As a result, LuaTeX-ja can control typesetting finer than \TeX. The following is the list of imaginary characters:

- `'boxbdd'`
  The beginning/ending of a hbox, and the beginning of a noindented (i.e., began by \noindent) paragraph. If a hbox b begins (resp. ends) a glue or kern between this “character” and a JChar, JAglue won’t be inserted before(resp. after) the hbox b. kanjiskip and xkanjiskip around a hbox.

- `'parbdd'`
  The beginning of an (indented) paragraph.

- `'jcharbdd'`
  A boundary between JChar and anything else.
Table 14. Commands for Japanese math fonts

<table>
<thead>
<tr>
<th>Japanese fonts</th>
<th>alphabetic fonts</th>
</tr>
</thead>
<tbody>
<tr>
<td>\jfam ∈ [0, 256)</td>
<td>\fam</td>
</tr>
<tr>
<td>jatextfont=((fam),(jfont cs))</td>
<td>\textfont(fam)=(font cs)</td>
</tr>
<tr>
<td>jascriptfont=((fam),(jfont cs))</td>
<td>\scriptfont(fam)=(font cs)</td>
</tr>
<tr>
<td>jascriptscriptfont=((fam),(jfont cs))</td>
<td>\scriptscriptfont(fam)=(font cs)</td>
</tr>
</tbody>
</table>

'alchar', 'nox_alchar'
(version 3 or later) A boundary between JAchar and ALchar.

'glue'
(version 3 or later) A boundary between JAchar, and, a glue or kern.

-1 The left/right boundary of an inline math formula.

Porting JFM from \(\text{p}$$\LaTeX$$\) See Japanese version of this manual.

7.6 Math font family

\(\text{\LaTeX}\) handles fonts in math formulas by 16 font families\(^{10}\), and each family has three fonts: \textfont, \scriptfont and \scriptscriptfont. \(\LaTeX\)-ja’s handling of Japanese fonts in math formulas is similar; Table 14 shows counterparts to \(\text{\LaTeX}\)’s primitives for math font families. There is no relation between the value of \fam and that of \jfam; with appropriate settings, one can set both \fam and \jfam to the same value. Here \(\text{\fam(cs)\text{\textfont}}\) etc. is a control sequence which is defined by \jfont, i.e., a horizontal Japanese font.

7.7 Callbacks

\(\LaTeX\)-ja also has several callbacks. These callbacks can be accessed via luatexbase.add_to_callback function and so on, as other callbacks.

\texttt{luatexja.load_jfm} callback

With this callback, one can overwrite JFMs. This callback is called when a new JFM is loaded.

\begin{verbatim}
  function (<table> jfm_info, <string> jfm_name)
    return <table> new_jfm_info
  end
\end{verbatim}

The argument \texttt{jfm_info} contains a table similar to the table in a JFM file, except this argument has \texttt{chars} field which contains character codes whose character class is not 0.

An example of this callback is the \texttt{ltjarticle} class, with forcefully assigning character class 0 to 'parbdd' in the JFM \texttt{jfm-min.lua}.

\texttt{luatexja.define_jfont} callback

This callback and the next callback form a pair, and you can assign characters which do not have fixed code points in Unicode to non-zero character classes. This \texttt{luatexja.define_font} callback is called just when new Japanese font is loaded.

\begin{verbatim}
  function (<table> jfont_info, <number> font_number)
    return <table> new_jfont_info
  end
\end{verbatim}

\texttt{jfont_info} has the following fields, \textit{which may not overwritten by a user:}

\texttt{size} The font size specified at \jfont in scaled points \((1 \text{ sp} = 2^{-16} \text{ pt})\).

\(^{10}\)Omega, Aleph, \(\LaTeX\) and \(\varepsilon\)\(\text{\LaTeX}\) can handle 256 families, but an external package is needed to support this in plain \(\text{\LaTeX}\) and \(\text{\LaTeX}\)-ja.

30

30
zw, zh, kanjiskip, xkanjiskip  These are scaled value of those specified by the JFM, by the font size.

\textbf{jfm}  The internal number of the JFM.

\textbf{var}  The value of \texttt{jfmvar} key, which is specified at \texttt{\jfont}. The default value is the empty string.

\textbf{chars}  The mapping table from character codes to its character classes.

The specification \texttt{[i].chars=\{\langle character\rangle, \ldots\}} in the JFM will be stored in this field as \texttt{chars=\{\langle character\rangle=i, \ldots\}}.

\textbf{char_type}  For \(i \in \omega\), \texttt{char_type}[i] is information of characters whose class is \(i\), and has the following fields:

- \texttt{width}, \texttt{height}, \texttt{depth}, \texttt{italic}, \texttt{down}, \texttt{left} are just scaled value of those specified by the JFM, by the font size.
- \texttt{align} is a number which is determined from \texttt{align} field in the JFM:

\[
\begin{cases}
1 & (\text{'right' in JFM}), \\
0.5 & (\text{'middle' in JFM}), \\
0 & (\text{otherwise}).
\end{cases}
\]

For \(i, j \in \omega\), \texttt{char_type}[i][j] stores a kern or a glue which will be inserted between character class \(i\) and class \(j\).

The returned table \texttt{new_jfont_info} also should include these fields, but you are free to add more fields (to use them in the \texttt{luatexja.find_char_class} callback). The \texttt{font_number} is a font number.

A good example of this and the next callbacks is the \texttt{luatexja-otf} package, supporting "AJ1-xxx" form for Adobe-Japan1 CID characters in a JFM. This callback doesn’t replace any code of Lua\TeX{}-ja.

\texttt{luatexja.find_char_class} callback

This callback is called just when Lua\TeX{}-ja is trying to determine which character class a character \texttt{chr_code} belongs. A function used in this callback should be in the following form:

\begin{verbatim}
function (<number> char_class, <table> jfont_info, <number> chr_code)
    if char_class==0 then return char_class
    else
        ....
    return (<number> new_char_class or 0)
end end
\end{verbatim}

The argument \texttt{char_class} is the result of Lua\TeX{}-ja’s default routine or previous function calls in this callback, hence this argument may not be 0. Moreover, the returned \texttt{new_char_class} should be as same as \texttt{char_class} when \texttt{char_class} is not 0, otherwise you will overwrite the Lua\TeX{}-ja’s default routine.

\texttt{luatexja.set_width} callback

This callback is called when Lua\TeX{}-ja is trying to encapsule a JAchar \texttt{glyph_node}, to adjust its dimension and position.

\begin{verbatim}
function (<table> shift_info, <table> jfont_info, <table> char_type)
    return <table> new_shift_info
end end
\end{verbatim}

The argument \texttt{shift_info} and the returned \texttt{new_shift_info} have \texttt{down} and \texttt{left} fields, which are the amount of shifting down/left the character in a scaled point.

A good example is test/valign.lua. After loading this file, the vertical position of glyphs is automatically adjusted; the ratio (\texttt{height} : \texttt{depth}) of glyphs is adjusted to be that of letters in the character class 0. For example, suppose that

- The setting of the JFM: (\texttt{height}) = 88x, (\texttt{depth}) = 12x (the standard values of Japanese OpenType fonts);
- The value of the real font: (\texttt{height}) = 28y, (\texttt{depth}) = 5y (the standard values of Japanese TrueType fonts).

31
Then, the position of glyphs is shifted up by
\[ \frac{88x}{88x + 12x} (28y + 5y) - 28y = \frac{26}{25} y = 1.04y. \]

8 Parameters

8.1 \texttt{\textbackslash ltjsetparameter}

As described before, \texttt{\textbackslash ltjsetparameter} and \texttt{\textbackslash ltjgetparameter} are commands for accessing most parameters of Lua\TeX-Ja. One of the main reasons that Lua\TeX-Ja didn't adopt the syntax similar to that of p\TeX (e.g., \texttt{\textbackslash prebreakpenalty} = 10000) is the position of hpack_filter callback in the source of Lua\TeX, see Section 12.

\texttt{\textbackslash ltjsetparameter} and \texttt{\textbackslash ltjglobalsetparameter} are commands for assigning parameters. These take one argument which is a key-value list. The difference between these two commands is the scope of assignment; \texttt{\textbackslash ltjsetparameter} does a local assignment and \texttt{\textbackslash ltjglobalsetparameter} does a global one by default. They also obey the value of \texttt{\textbackslash globaldefs}, like other assignments.

The following is the list of parameters which can be specified by the \texttt{\textbackslash ltjsetparameter} command. [\texttt{\textbackslash cs}] indicates the counterpart in p\TeX, and symbols beside each parameter has the following meaning:

- “∗”: values at the end of a paragraph or a hbox are adopted in the whole paragraph or the whole hbox.
- “†”: assignments are always global.

\texttt{\textbackslash jcharwidowpenalty} = (\texttt{penalty})* [\texttt{\textbackslash jcharwidowpenalty}]

Penalty value for suppressing orphans. This penalty is inserted just after the last \texttt{\textbackslash JAtextchar} which is not regarded as a (Japanese) punctuation mark.

\texttt{\textbackslash kcatcode} = \{⟨\texttt{chr\_code}⟩, ⟨\texttt{natural number}⟩\}∗

An additional attributes which each character whose character code is ⟨\texttt{chr\_code}⟩ has. At version 20120506.0 or later, the lowermost bit of ⟨\texttt{natural number}⟩ indicates whether the character is considered as a punctuation mark (see the description of \texttt{jcharwidowpenalty} above).

\texttt{\textbackslash prebreakpenalty} = \{⟨\texttt{chr\_code}⟩, ⟨\texttt{penalty}⟩\}∗ [\texttt{\textbackslash prebreakpenalty}]

Set a penalty which is inserted automatically before the character ⟨\texttt{chr\_code}⟩, to prevent a line starts from this character. For example, a line cannot started with one of closing brackets “]”, so Lua\TeX-Ja sets
\[
\texttt{\textbackslash ltjsetparameter}\{\texttt{prebreakpenalty} = \{` \}, 10000\}\}
\]

by default.

p\TeX has following restrictions on \texttt{\textbackslash prebreakpenalty} and \texttt{\textbackslash postbreakpenalty}, but they don’t exist in Lua\TeX-Ja:

- Both \texttt{\textbackslash prebreakpenalty} and \texttt{\textbackslash postbreakpenalty} cannot be set for the same character.
- We can set \texttt{\textbackslash prebreakpenalty} and \texttt{\textbackslash postbreakpenalty} up to 256 characters.

\texttt{\textbackslash postbreakpenalty} = \{⟨\texttt{chr\_code}⟩, ⟨\texttt{penalty}⟩\}∗ [\texttt{\textbackslash postbreakpenalty}]

Set a penalty which is inserted automatically after the character ⟨\texttt{chr\_code}⟩, to prevent a line ends with this character.

\texttt{\textbackslash jatextfont} = \{⟨\texttt{jfam}⟩, ⟨\texttt{jfont\_cs}⟩\}∗ [\texttt{\textbackslash textfont in \TeX}]

\texttt{\textbackslash jascriptfont} = \{⟨\texttt{jfam}⟩, ⟨\texttt{jfont\_cs}⟩\}∗ [\texttt{\textbackslash scriptfont in \TeX}]

\texttt{\textbackslash jascriptscriptfont} = \{⟨\texttt{jfam}⟩, ⟨\texttt{jfont\_cs}⟩\}∗ [\texttt{\textbackslash scriptscriptfont in \TeX}]

\texttt{\textbackslash yjabaselineshift} = ⟨\texttt{dimen}⟩

\texttt{\textbackslash yalbaselineshift} = ⟨\texttt{dimen}⟩ [\texttt{\baselineshift}]
\texttt{tjabaselineshift} = (\texttt{dimen})
\texttt{talbaselineshift} = (\texttt{dimen}) [\texttt{tbaselineshift}]
\texttt{jxspmode} = \{(\texttt{chr\_code}), (\texttt{mode})\}*

Set whether inserting \texttt{xkanjiskip} is allowed before/after a \texttt{JAchar} whose character code is \texttt{chr\_code}. The followings are allowed for \texttt{(mode)}:

0, inhibit Insertion of \texttt{xkanjiskip} is inhibited before the character, nor after the character.
1, preonly Insertion of \texttt{xkanjiskip} is allowed before the character, but not after.
2, postonly Insertion of \texttt{xkanjiskip} is allowed after the character, but not before.
3, allow Insertion of \texttt{xkanjiskip} is allowed both before the character and after the character. This is the default value.

This parameter is similar to the \texttt{\inhibitxspcode} primitive of \LaTeX, but not compatible with \texttt{\inhibitxspcode}.

\texttt{alxspmode} = \{(\texttt{chr\_code}), (\texttt{mode})\} [\xspcode]

Set whether inserting \texttt{xkanjiskip} is allowed before/after a \texttt{ALchar} whose character code is \texttt{chr\_code}. The followings are allowed for \texttt{(mode)}:

0, inhibit Insertion of \texttt{xkanjiskip} is inhibited before the character, nor after the character.
1, preonly Insertion of \texttt{xkanjiskip} is allowed before the character, but not after.
2, postonly Insertion of \texttt{xkanjiskip} is allowed after the character, but not before.
3, allow Insertion of \texttt{xkanjiskip} is allowed before the character and after the character. This is the default value.

Note that parameters \texttt{jxspmode} and \texttt{alxspmode} share a common table, hence these two parameters are synonyms of each other.

\texttt{autospacing} = (\texttt{bool}) [\texttt{autospacing}]
\texttt{autoxspacing} = (\texttt{bool}) [\texttt{autoxspacing}]
\texttt{kanjiskip} = (\texttt{skip}) [\texttt{kanjiskip}]

The default glue which inserted between two \texttt{JAchar}s. Changing current Japanese font does not alter this parameter, as \LaTeX.

If the natural width of this parameter is \texttt{\maxdimen}, Lua\LaTeX-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 7.5).

\texttt{xkanjiskip} = (\texttt{skip}) [\texttt{xkanjiskip}]

The default glue which inserted between a \texttt{JAchar} and an \texttt{ALchar}. Changing current font does not alter this parameter, as \LaTeX.

As \texttt{kanjiskip}, if the natural width of this parameter is \texttt{\maxdimen}, Lua\LaTeX-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 7.5).

\texttt{differentjfm} = (\texttt{mode})

Specify how glues/kerns between two \texttt{JAchar}s whose JFM (or size) are different. The allowed arguments are the followings:

average, both, large, small, pleft, pright, paverage

The default value is paverage. ...

\texttt{jacharrange} = (\texttt{ranges})
\texttt{kansujichar} = \{(\texttt{digit}), (\texttt{chr\_code})\} [\texttt{kansujichar}]
\texttt{direction} = (\texttt{dir}) (always local)

Assigning to this parameter has the same effect as \texttt{\yoko} (if \texttt{dir} = 4), \texttt{\tate} (if \texttt{dir} = 3), \texttt{\dtou} (if \texttt{dir} = 1) or \texttt{\utod} (if \texttt{dir} = 11). If the argument \texttt{dir} is not one of 4, 3, 1 nor 11, the behavior of this assignment is undefined.
8.2 \texttt{\textbackslash ltjgetparameter}

\texttt{\textbackslash ltjgetparameter} is a control sequence for acquiring parameters. It always takes a parameter name as first argument.

\begin{itemize}
  \item \texttt{\textbackslash ltjgetparameter{differentjfm}}, \texttt{\textbackslash ltjgetparameter{autospacing}}, \texttt{\textbackslash ltjgetparameter{kanjiskip}}, \texttt{\textbackslash ltjgetparameter{prebreakpenalty}{\textbackslash paverage}}, \texttt{\textbackslash ltjgetparameter{differentjfm}}, \texttt{\textbackslash ltjgetparameter{autospacing}}, \texttt{\textbackslash ltjgetparameter{prebreakpenalty}{\textbackslash paverage}}, \texttt{\textbackslash ltjgetparameter{prebreakpenalty}{\textbackslash paverage}, 1, 0.0pt plus 0.4pt minus 0.5pt, 10000.}
  \item The return value of \texttt{\textbackslash ltjgetparameter} is always a string, which is outputted by tex.write(). Hence any character other than space \texttt{"\textquotesingle(U+0020)} has the category code 12 (other), while the space has 10 (space).
\end{itemize}

\begin{itemize}
  \item If first argument is one of the following, no additional argument is needed.
    \texttt{jcharwidowpenalty}, \texttt{yjabaselineshift}, \texttt{yalbaselineshift}, \texttt{autospacing}, \texttt{autoxspacing}, \texttt{kanjiskip}, \texttt{xkanjiskip}, \texttt{differentjfm}, \texttt{direction}
  \item Note that \texttt{\textbackslash ltjgetparameter{autospacing}} and \texttt{\textbackslash ltjgetparameter{autoxspacing}} returns 1 or 0, not true nor false.
  \item If first argument is one of the following, an additional argument—a character code, for example—is needed.
    \texttt{kcatcode}, \texttt{prebreakpenalty}, \texttt{postbreakpenalty}, \texttt{jaxspmode}, \texttt{alxspmode}
  \item \texttt{\textbackslash ltjgetparameter{jaxspmode}{\textbackslash jacharrange}{\textbackslash chartorange}{\langle chr\, code\rangle}} returns 0, 1, 2, or 3, instead of preonly etc.
  \item For an integer \texttt{(digit)} between 0 and 9, \texttt{\textbackslash ltjgetparameter{kansujichar}{\langle digit\rangle}} returns the character code of the result of \texttt{\kansuji{(digit)}}.
  \item \texttt{\textbackslash ltjgetparameter{adjustdir}} returns a integer which represents the direction of the surrounding vertical list. As \texttt{direction}, the return value 1 means \texttt{down-to-up} direction, 3 means \texttt{tate} direction (vertical typesetting), and 4 means \texttt{yoko} direction (horizontal typesetting).
  \item For an integer \texttt{\langle reg\, num\rangle} between 0 and 65535, \texttt{\textbackslash ltjgetparameter{boxdim}{\langle reg\, num\rangle}} returns the direction of \texttt{\box{(reg\, num)}}. If this box register is void, the returned value is zero.
  \item The following parameter names \textbf{cannot be specified} in \texttt{\textbackslash ltjgetparameter}.
    \texttt{jtextfont}, \texttt{jscriptfont}, \texttt{jscriptscriptfont}, \texttt{chartorange}
  \item \texttt{\textbackslash ltjgetparameter{chartorange}{\langle chr\, code\rangle} \textbackslash ltjgetparameter{chartorange}{\langle chr\, code\rangle} \textbackslash ltjgetparameter{chartorange}{\langle chr\, code\rangle}} returns the range number which \texttt{\langle chr\, code\rangle} belongs to (although there is no parameter named \texttt{"chartorange"}).
  \item If \texttt{\langle chr\, code\rangle} is between 0 and 127, this \texttt{\langle chr\, code\rangle} does not belong to any character range. In this case, \texttt{\textbackslash ltjgetparameter{chartorange}{\langle chr\, code\rangle} \textbackslash ltjgetparameter{chartorange}{\langle chr\, code\rangle} \textbackslash ltjgetparameter{chartorange}{\langle chr\, code\rangle}} returns \texttt{\textbackslash paverage}. Hence, one can know whether \texttt{\langle chr\, code\rangle} is \texttt{JChar} or not by the following:
    \texttt{\textbackslash ltjgetparameter{\textbackslash paverage}\textbackslash ltjgetparameter{\textbackslash paverage}\textbackslash ltjgetparameter{\textbackslash paverage}}
  \item Because the returned value is string, the following conditionals do not work if \texttt{kanjiskip} (or \texttt{xkanjiskip}) has the stretch part or the shrink part.
    \texttt{\textbackslash ifdim\textbackslash ltjgetparameter{kanjiskip}\textbackslash ifdim\textbackslash ltjgetparameter{xkanjiskip}}
\end{itemize}

The correct way is using a temporary register.

\begin{verbatim}
\@tempskipa=\textbackslash ltjgetparameter{kanjiskip}\ifdim\@tempskipa>\z@ ... \fi
\@tempskipa=\textbackslash ltjgetparameter{xkanjiskip}\ifdim\@tempskipa>\z@ ... \fi
\end{verbatim}
8.3 Alternative Commands to $\backslash \texttt{ltjsetparameter}$

The basic method to set parameters of Lua\TeX{}-ja is to use $\backslash \texttt{ltjsetparameter}$ or $\backslash \texttt{ltjglobalsetparameter}$. However, these commands are slow, because they parse a key-value list, so several alternative commands are used in Lua\TeX{}-ja. This subsection is not for general Lua\TeX{}-ja users.

■ Setting $\texttt{kanjiskip}$ or $\texttt{xkanjiskip}$ In \texttt{ltjclasses}, every size-changing command such as $\backslash \Large \texttt{kanjiskip}$ and $\backslash \texttt{xkanjiskip}$. But a simple implementation, as the code below, is slow since two key-value lists are parsed by $\backslash \texttt{ltjsetparameter}$:

\begin{verbatim}
\texttt{ltjsetparameter}{kanjiskip=0\zw plus .1\zw minus .01\zw}
\@tempskipa=\texttt{ltjgetparameter}{xkanjiskip}
\ifdim\@tempskipa>\z@
  \if@slide
    \texttt{ltjsetparameter}{xkanjiskip=0.1em}
  \else
    \texttt{ltjsetparameter}{xkanjiskip=0.25em plus 0.15em minus 0.06em}
  \fi
\fi
\end{verbatim}

Hence, Lua\TeX{}-ja defines more primitive commands, namely $\backslash \texttt{ltj@setpar@global}$, $\backslash \texttt{ltjsetkanjiskip}$, and $\backslash \texttt{ltjsetxkanjiskip}$. Here

\begin{verbatim}
\texttt{ltj@setpar@global}{\texttt{ltjsetkanjiskip}10pt}
\end{verbatim}

and $\backslash \texttt{ltjsetparameter}{\texttt{kanjiskip}=10pt}$ has the same effect. The actual code of \texttt{ltjclasses} is shown below:

\begin{verbatim}
\texttt{ltjsetparameter}{kanjiskip=0\zw plus .1\zw minus .01\zw}
\@tempskipa=\texttt{ltjgetparameter}{xkanjiskip}
\ifdim\@tempskipa>\z@
  \if@slide
    \texttt{ltjsetxkanjiskip}.1em
  \else
    \texttt{ltjsetxkanjiskip}.25em plus 0.15em minus 0.06em
  \fi
\fi
\end{verbatim}

Note that using $\backslash \texttt{ltjsetkanjiskip}$ or $\backslash \texttt{ltjsetxkanjiskip}$ alone, that is, without executing $\backslash \texttt{ltj@setpar@global}$ in advance, is not supported.

9 Other Commands for plain \TeX{} and \LaTeX{} 2ɛ

9.1 Commands for compatibility with \p\LaTeX{}

The following commands are implemented for compatibility with \p\LaTeX{}. Note that the former five commands don’t support JIS X 0213, but only JIS X 0208. The last $\backslash \texttt{kansuji}$ converts an integer into its Chinese numerals.

$\backslash \texttt{kuten}$, $\backslash \texttt{jis}$, $\backslash \texttt{euc}$, $\backslash \texttt{jis}$, $\backslash \texttt{ucs}$, $\backslash \texttt{kansuji}$

These six commands takes an internal integer, and returns a string.

\begin{enumerate}
  \item $\newcount\hoge$
  \item $\hoge="2423 \%"$
  \item $\the\hoge, \backslash \texttt{kansuji}\hoge$
  \item $\jis\hoge, \backslash \texttt{char}\jis\hoge$
  \item $\backslash \texttt{kansuji1701}$
\end{enumerate}

To change characters of Chinese numerals for each digit, set $\texttt{kansujichar}$ parameter:

\begin{enumerate}
  \item $\backslash \texttt{ltjsetparameter}\{\texttt{kansujichar}=\{1, `壹}\}$
  \item $\backslash \texttt{ltjsetparameter}\{\texttt{kansujichar}=\{7, `漆}\}$
  \item $\backslash \texttt{ltjsetparameter}\{\texttt{kansujichar}=\{0, `零}\}$
  \item $\backslash \texttt{kansuji1701}$
\end{enumerate}

9251, 二五一
12355, い
一七〇一
壹漆零壹

35
9.2 \inhibitglue

\inhibitglue suppresses the insertion of JAgue. The following is an example, using a special JFM that there will be a glue between the beginning of a box and "あ", and also between "あ" and "ウ".

\begin{verbatim}
\jfont\g=HaranoAjiMincho-Regular:jfm=test \g
\fbox{\hbox{あウあ\inhibitglue ウ}}
\inhibitglue\par\noindent あ1
\par\noindent \inhibitglue あ2
\par\hrule\noindent あ office
\end{verbatim}

With the help of this example, we remark the specification of \inhibitglue:

- The call of \inhibitglue in the (internal) vertical mode is simply ignored.
- The call of \inhibitglue in the (restricted) horizontal mode is only effective on the spot; does not get over boundary of paragraphs. Moreover, \inhibitglue cancels ligatures and kernings, as shown in the last line of above example.
- The call of \inhibitglue in math mode is just ignored.

9.3 \ltjfakeboxbdd, \ltjfakeparbegin

Sometimes 'parbdd' and 'boxbdd' specifications look like "fail", especially in paragraphs inside list environments. This is because everypar inserts some nodes such as boxes and kerns, so the "first letter" in a paragraph is in fact not the first letter.

\begin{verbatim}
\parindent1\zw
\noindent ああああああああ\par % for comparison
「ああああああ\par % normal paragraph
「ああああああ
\everypar{null}
「ああああああ\par % ???
\end{verbatim}

\ltjfakeboxbdd and \ltjfakeparbegin primitives resolve this situation.

- \ltjfakeparbegin creates a node which indicates "beginning of an indented paragraph" to the insertion process of JAgue.
- \ltjfakeboxbdd creates a node which indicates "beginning/ending of a box" to the insertion process of JAgue.

As an example, the example above can be improved as follows:

\begin{verbatim}
\parindent1\zw
\noindent ああああああああ\par % for comparison
「ああああああ\par % normal paragraph
「ああああああ
\everypar{null}\ltjfakeparbegin
「ああああああ \par
\end{verbatim}

9.4 \ltjdeclarealtfont

Using \ltjdeclarealtfont, one can "compose" more than one Japanese fonts. This \ltjdeclarealtfont uses in the following form:

\begin{verbatim}
\ltjdeclarealtfont{base_font_cs}{alt_font_cs}{{(range)}}
\end{verbatim}

where (base_font_cs) and (alt_font_cs) are defined by \jfont. Its meaning is

If the current Japanese font is (base_font_cs), characters which belong to (range) is typeset by another Japanese font (alt_font_cs), instead of (base_font_cs).
Here (range) is a comma-separated list of character codes, but also accepts negative integers: \( -n \) \((n \geq 1)\) means that all characters of character classes \( n \), with respect to JFM used by \langle base\_font\_cs \rangle. Note that characters which do not exist in \langle alt\_font\_cs \rangle are ignored.

For example, if \texttt{\hoge} uses \texttt{jfm-ujis.lua}, the standard JFM of Lua\TeX-ja, then
\begin{verbatim}
\ltjdeclarealtfont\hoge\piyo{"3000--30FF, {-1}--{-1}}
\end{verbatim}
does

If the current Japanese font is \texttt{\hoge}, U+3000–U+30FF and characters in class 1 (ideographic opening brackets) are typeset by \texttt{\piyo}.

Note that specifying negative numbers needs specification like \{-1}--{-1}, because simple \(-1\) is treated as the range between 0 and 1.

\begin{verbatim}
\1\gtfamily\large
\2\&\char\¶,\ltjachar\¶,\ltjjachar\¶\%
\3\alph\a,\ltjachar\a,\ltjjachar\a\%

\end{verbatim}

\section{Commands for \LaTeX2\epsilon}

\subsection{Loading Japanese fonts in \LaTeX2\epsilon}

From version 20190107, Lua\TeX-ja does not load Japanese fonts for horizontal direction and that for vertical direction at same time, to reduce the number of loaded fonts. This will save time for typesetting and memory consumption of Lua side ([11]).

\begin{itemize}
\item \texttt{\selectfont} loads (and chooses) only the Japanese font for current direction, and does not load the Japanese font for other direction (Lua\TeX-ja only detects its size and JFM, to calculate the amount of shifting the baseline).
\item Direction changing commands (\texttt{\yoko}, \texttt{\tate}, \texttt{\dtou}, \texttt{\utod}) are patched to include the following process:

If the Japanese font for new direction is not loaded, Lua\TeX-ja loads it automatically. Original commands are saved as \texttt{\ltj@@orig@yoko} etc.
\item Specifying Japanese font command which is defined by \texttt{\jfont}, \texttt{\tfont}, or \texttt{\DeclareFixedFont} directly actually loads (and selects) the Japanese font. For example, \texttt{\Jchars} in \texttt{\box0} will be typeset in \texttt{\HOGE}, in the following code:

\begin{verbatim}
% in horizontal direction \yoko
\DeclareFixedFont\HOGE\{JT3\}\{gt\}\{m\}\{n\}\{12\} % JT3: for vertical direction
\HOGE\setbox0=\hbox{\tateあいう}
\end{verbatim}
\end{itemize}

\subsection{Patch for NFSS2}

Japanese patch for NFSS2 in Lua\TeX-ja is based on p1fonts.dtx which plays the same role in p\LaTeX2\epsilon. We will describe commands which are not described in Subsection 3.1.

\textbf{additional dimensions}

Like p\LaTeX2\epsilon, Lua\TeX-ja defines the following dimensions for information of current Japanese font:

\begin{verbatim}
\cht (height), \cdp (depth), \cHT (sum of former two),
\cwd (width), \cvs (lineskip), \chs (equals to \cwd)
\end{verbatim}

and its \texttt{\normalsize} version:
Note that \texttt{\textwidth} and \texttt{\textheight} may differ from \texttt{\zwidth} and \texttt{\zh} respectively. On the one hand the former dimensions are determined from a character whose character class is zero, but on the other hand \texttt{\zwidth} and \texttt{\zh} are specified by JFM.

\begin{verbatim}
\DeclareYokoKanjiEncoding{⟨encoding⟩}{⟨text-settings⟩}{⟨math-settings⟩}
\DeclareTateKanjiEncoding{⟨encoding⟩}{⟨text-settings⟩}{⟨math-settings⟩}
\end{verbatim}

In NFSS2 under LuaTEX-ja, distinction between alphabetic fonts and Japanese fonts are only made by their encodings. For example, encodings OT1 and T1 are encodings for alphabetic fonts, and Japanese fonts cannot have these encodings. These command define a new encoding scheme for Japanese font families.

\begin{verbatim}
\DeclareKanjiEncodingDefaults{⟨text-settings⟩}{⟨math-settings⟩}
\DeclareKanjiSubstitution{⟨encoding⟩}{⟨family⟩}{⟨series⟩}{⟨shape⟩}
\DeclareErrorKanjiFont{⟨encoding⟩}{⟨family⟩}{⟨series⟩}{⟨shape⟩}{⟨size⟩}
\end{verbatim}

The above 3 commands are just the counterparts for \DeclareFontEncodingDefaults and others.

\begin{verbatim}
\reDeclareMathAlphabet{⟨unified-cmd⟩}{⟨al-cmd⟩}{⟨ja-cmd⟩}
\DeclareRelationFont{⟨ja-encoding⟩}{⟨ja-family⟩}{⟨ja-series⟩}{⟨ja-shape⟩}
{⟨al-encoding⟩}{⟨al-family⟩}{⟨al-series⟩}{⟨al-shape⟩}
\end{verbatim}

This command sets the “accompanied” alphabetic font (given by the latter 4 arguments) with respect to a Japanese font given by the former 4 arguments.

\begin{verbatim}
\SetRelationFont
\end{verbatim}

This command is almost same as \DeclareRelationFont, except that this command does a local assignment, where \DeclareRelationFont does a global assignment.

\begin{verbatim}
\userelfont
\end{verbatim}

(Only) at the next call of \selectfont, change current alphabetic font encoding/family/... to the ‘accompanied’ alphabetic font family with respect to current Japanese font family, which was set by \DeclareRelationFont or \SetRelationFont.

The following is an example of \SetRelationFont and \userelfont:

\begin{verbatim}
\makeatletter
\SetRelationFont{JY3}{\k@family}{m}{n}{TU}{lmss}{m}{n}
\userelfont\selectfontあいう abc
\end{verbatim}

\begin{verbatim}
\adjustbaseline
\end{verbatim}

In pLaTeX 2ε, \adjustbaseline sets \texttt{\baselinestretch} to match the vertical center of “M” and that of “漢” in vertical typesetting:

\begin{verbatim}
\baselinestretch ← (h_M + d_M) - (h_漢 + d_漢) + d_漢 - d_M,
\end{verbatim}

where \texttt{h_a} and \texttt{d_a} denote the height of “a” and the depth, respectively. In LuaTEX-ja, this \adjustbaseline does similar task, namely setting the \texttt{talbaselineshift} parameter (a Japanese character whose character class is zero is used, instead of “漢”).

\begin{verbatim}
\fontfamily{⟨family⟩}
\fontshape{⟨shape⟩}, \fontshapeforce{⟨shape⟩}
\end{verbatim}

As in pLaTeX 2ε, this command changes current font family (alphabetic, Japanese, or both) to \texttt{⟨family⟩}. See Subsection 10.3 for detail.

\begin{verbatim}
\fontfamily{⟨family⟩}
\fontshape{⟨shape⟩}, \fontshapeforce{⟨shape⟩}
\end{verbatim}

As in pLaTeX 2ε, this command changes current alphabetic font shape according to shape change rules. Traditionally, \texttt{\fontshape} changes also current Japanese font shape always. However, this leads a lot of \texttt{\fontshape} font warning like
日本国民は、正当に選挙された国会における代表者を通じて行動し、……

Figure 7. An example of DECLAREALTERNATEKANJIFONT

Font shape `JY3/mc/m/it' undefined using `JY3/mc/m/n' instead on ....

when \itshape is called, because almost all Japanese fonts only have shape "n", and \itshape calls \fontshape.

LuaTEx-ja 20200323.0 change the behavior. Namely, \fontshape{⟨shape⟩} and \fontshapeforce{⟨shape⟩} change current Japanese font shape, only if the required shape (according to shape changing rules) or ⟨shape⟩ is available in current Japanese font family/series. When this is not the case, an info such as

Kanji font shape JY3/mc/m/it' undefined
No change on ...

is issued instead of a warning.

\kanjishape{⟨shape⟩}, \kanjishapeforce{⟨shape⟩}
\kanjishape{⟨shape⟩} changes current Japanese font shape according to shape change rules, and \kanjishapeforce{⟨shape⟩} changes current Japanese font shape to ⟨shape⟩, regardless of the rules. Hence \kanjishape{it} produces a warning

Font shape `JY3/mc/m/it' undefined using `JY3/mc/m/n' instead on ....

which is not produced by \fontshape{it}.

\DeclareAlternateKanjifont{⟨base-encoding⟩}{⟨base-family⟩}{⟨base-series⟩}{⟨base-shape⟩}{⟨alt-encoding⟩}{⟨alt-family⟩}{⟨alt-series⟩}{⟨alt-shape⟩}{⟨range⟩}

As \ltjdeclarealtfont (Subsection 9.4), characters in ⟨range⟩ of the Japanese font (we say the base font) which specified by first 4 arguments are typeset by the Japanese font which specified by fifth to eighth arguments (we say the alternate font). An example is shown in Figure 7.

• In \ltjdeclarealtfont, the base font and the alternate font must be already defined. But this \DeclareAlternateKanjifont is not so. In other words, \DeclareAlternateKanjifont is effective only after current Japanese font is changed, or only after \selectfont is executed.

• ...

Furthermore, LuaTEx-ja applies patches which enables NFSS2 commands, such as \DeclareSymbolFont and \SetSymbolFont, to specify Japanese fonts as math fonts.

Specifying disablejfam option in \usepackage prevents applying these patches. Hence one cannot write Japanese Characters in math mode directly if disablejfam option is specified. The code below does not work either:

\DeclareSymbolfont{mincho}{JY3}{mc}{m}{n}
\DeclareSymbolfontAlphabet{\mathmc}{mincho}
10.3 Detail of \fontfamily command

In this subsection, we describe when \fontfamily\textit{(family)} changes current Japanese/alphabetic font family. Basically, current Japanese/alphabetic family is changed to \textit{(family)} if it is recognized as a Japanese font family, and similar with alphabetic font family. There is a case that current Japanese/alphabetic font family are both changed to \textit{(family)}, and another case that \textit{(family)} isn’t recognized as a Japanese/alphabetic font family either.

\textbf{Recognition as Japanese font family} First, whether Japanese font family will be changed is determined in following order. This order is very similar to \fontfamily in \LaTeX 2e, but we re-implemented in Lua. We use an auxiliary list \textit{N}_J.

1. If the family \textit{(family)} has been defined already by \texttt{\DeclareKanjiFamily}, \textit{(family)} is recognized as a Japanese font family. Note that \textit{(family)} need not be defined under current Japanese font encoding.
2. If the family \textit{(family)} has been listed in a list \textit{N}_J, this means that \textit{(family)} is not a Japanese font family.
3. If the \texttt{luatexja-fontspec} package is loaded, we stop here, and \textit{(family)} is not recognized as a Japanese font family.

If the \texttt{luatexja-fontspec} package is not loaded, now \LaTeX-ja looks whether there exists a Japanese font encoding \textit{(enc)} such that a font definition named \textit{(enc)\texttt{family}}. \texttt{fd} (the file name is all lowercase) exists. If so, \textit{(family)} is recognized as a Japanese font family (the font definition file won’t be loaded here). If not, \textit{(family)} is not a Japanese font family, and \textit{(family)} is appended to the list \textit{N}_J.

\textbf{Recognition as alphabetic font family} Next, whether alphabetic font family will be changed is determined in following order. We use auxiliary lists \textit{F}_A and \textit{N}_A.

1. If the family \textit{(family)} has been listed in a list \textit{F}_A, \textit{(family)} is recognized as an alphabetic font family.
2. If the family \textit{(family)} has been listed in a list \textit{N}_A, this means that \textit{(family)} is not an alphabetic font family.
3. If a Japanese font encoding \textit{(enc)} has been defined under it, \textit{(family)} is recognized as an alphabetic font family, and to memorize this, \textit{(family)} is appended to the list \textit{F}_A.
4. Now \LaTeX-ja looks whether there exists an alphabetic font encoding \textit{(enc)} such that a font definition named \textit{(enc)\texttt{family}}. \texttt{fd} (the file name is all lowercase) exists. If so, current alphabetic font family will be changed to \textit{(family)} (the font definition file won’t be loaded here). If not, current alphabetic font family won’t be changed, and \textit{(family)} is appended to the list \textit{N}_A.

Also, each call of \texttt{\DeclareFontFamily} after loading of \LaTeX-ja makes the second argument \textit{(family)} is appended to the list \textit{F}_A.

The above order is very similar to \fontfamily in \LaTeX 2e, but more complicated (clause 3.). This is because \LaTeX 2e is a \texttt{format} however \LaTeX-ja is not, hence \LaTeX-ja does not know calls of \texttt{\DeclareFontFamily} before itself is loaded.

\textbf{Remarks} Of course, there is a case that \textit{(family)} is not recognized as a Japanese font family, nor an alphabetic font family. In this case, \LaTeX-ja treats ”the argument \textit{(family)} is wrong”, so set both current alphabetic and Japanese font family to \textit{(family)}, to use the default family for font substitution.

10.4 Notes on \DeclareTextSymbol

From \LaTeX 2017/01/01, the standard encoding of \LaTeX is changed to the \texttt{TU} encoding. This means that symbols defined by T1 and TS1 encodings can be used without loading any package. To produces these symbols in alphabetic fonts in \LaTeX-ja, \LaTeX-ja patches \texttt{\DeclareTextSymbol}, and reloads \texttt{tuenc.def}.

Under original definition of \texttt{\DeclareTextSymbol}, internal commands which is defined by \texttt{\DeclareTextSymbol} (such as \texttt{\texttt{T1}\texttt{\textquotedblleft}}} are \texttt{chardef} tokens. However, this no longer holds in \LaTeX-ja; for example, the meaning of \texttt{\texttt{TU}\texttt{\textquotedblleft}} is \texttt{\ltjalchar8220}.

横組のテスト
縦組のテスト

10.5 \strutbox

As p\TeX\ (2017/04/08 or later), \strutbox is a macro which is expanded to one of \ystrutbox, \tstrutbox, and \dstrutbox (all of them are shown in Table 15), according to the current direction. Similarly, \strut now uses one of these boxes.

11 Addon packages

Lua\TeX-ja has several addon packages. These addons are written as \TeX packages, but luatexja-otf and luatexja-adjust can be loaded in plain Lua\TeX by \input.

11.1 luatexja-fontspec

As described in Subsection 3.2, this optional package provides the counterparts for several commands defined in the fontspec package (requires fontspec v2.4). In addition to OpenType font features in the original fontspec, the following "font features" specifications are allowed for the commands of Japanese version:

CID=(⟨name⟩), \JFN=(⟨name⟩), \JFN-var=(⟨name⟩)

These 3 keys correspond to cid, jfm and jfmvar keys for \jfont and \tfont respectively. See Subsections 7.1 and 7.4 for details of cid, jfm and jfmvar keys.

The CID key is effective only when with NoEmbed described below. The same JFM cannot be used in both horizontal Japanese fonts and vertical Japanese fonts, hence the JFM key will be actually used in YokoFeatures and TateFeatures keys.

NoEmbed

By specifying this key, one can use “name-only” Japanese font which will not be embedded in the output PDF file. See Subsection 7.4.

Kanjiskip=(⟨bool⟩)

TateFeatures=(⟨features⟩), TateFont=(⟨font⟩)

The TateFeatures key specifies font features which are only turned on in vertical writing, such as Style=VerticalKana (vkna feature). Similarly, the TateFont key specifies the Japanese font which will be used only in vertical writing. A demonstrarion is shown in Figure 8.
日本国民は、正当に選挙された国会における代表者を通じて行動し、われらとわれらの子孫のために、
諸国民との協和による成果と、わが国全土にわたって自由のもたらす恵沢を確保し、……

日本国民は、正当に選挙された国会における代表者を通じて行動し、われらとわれらの子孫のために、
諸国民との協和による成果と、わが国全土にわたって自由のもたらす恵沢を確保し、……

Figure 9. An example of AltFont

YokoFeatures={⟨features⟩}
The YokoFeatures key specifies font features which are only turned on in horizontal writing. A
demonstration is shown in Figure 8.

AltFont
As \ltjdeclarealtfont (Subsection 9.4) and \DeclareAlternateKanjiFont (Subsection 10.2), with
this key, one can typeset some Japanese characters by a different font and/or using different features.
The AltFont feature takes a comma-separated list of comma-separated lists, as the following:

AltFont = {
  ... 
  { Range=⟨range⟩, ⟨features⟩ },
  { Range=⟨range⟩, Font=⟨font name⟩, ⟨features⟩ },
  { Range=⟨range⟩, Font=⟨font name⟩ }
  ...
}

Each sublist should have the Range key (sublist which does not contain Range key is simply ignored).
A demonstration is shown in Figure 9.

Remarks on AltFont, YokoFeatures, TateFeatures keys
In AltFont, YokoFeatures, TateFeatures keys, one cannot specify per-shape settings such as
BoldFeatures. For example,

AltFont = {
  { Font=HogeraMin-Light, BoldFont=HogeraMin-Bold,
    Range="3000-"30FF, BoldFeatures={Color=FF1900} }
}

does not work. Instead, one have to write

UprightFeatures = {
  AltFont = { { Font=HogeraMin-Light, Range="3000-"30FF, } },
},
BoldFeatures = {
  AltFont = { { Font=HogeraMin-Bold, Range="3000-"30FF, Color=FF1900 } },
}

On the other hand, YokoFeatures, TateFeatures and TateFont keys can be specified in each list in
the AltFont key. Also, one can specify AltFont inside YokoFeatures, TateFeatures.

Note that features which are specified in YokoFeatures and TateFeatures are always interpreted after
other "direction-independent" features. This explains why \addjfontfeatures at line 6 in Figure 8 has no
effect, because a color specification is already done in YokoFeatures and TateFeatures keys.
11.2 luatexja-otf

This optional package supports typesetting glyphs by specifying a CID number. The package luatexja-otf offers the following 2 low-level commands:

\CID{(number)}
Typeset a glyph whose CID number is \textit{(number)}. If the Japanese font is neither Adobe-Japan1, Adobe-GB1, Adobe-CNS1, Adobe-Korea1, nor Adobe-KR CID-keyed font, Lua\TeX-ja treats that \textit{(number)} is a CID number of Adobe-Japan1 character collection, and tries to typeset a "most suitable glyph".

Note that if the Japanese font is loaded using the HarfBuzz library, this \CID{} command does not work.

\UTF{(hex_number)}
Typeset a character whose character code is \textit{(hex_number)} (in hexadecimal). This command is similar to \texttt{char"\textit{(hex_number)}}

This package automatically loads \texttt{luatexja-ajmacros.sty}, which is slightly modified version of \texttt{ajmacros.sty}\textsuperscript{11}. Hence one can use macros which are defined in \texttt{ajmacros.sty}, such as \texttt{\aj半角}.

\textbf{Remarks} Characters by \CID{} and \UTF{} commands are different from ordinary characters in the following points:

- Always treated as JAchars.
- In vertical direction, vert/vrt2 feature are automatically applied to characters by \UTF{}, regardless these feature are not activated in current Japanese font.
- Processes for supporting other OpenType features (for example, glyph replacement and kerning) by the luaotfload package is not performed to these characters.

\textbf{Additional syntax of JFM} The package luatexja-otf extends the syntax of JFM; the entries of \texttt{chars} table in JFM now allows a string in the form 'AJ1-xxx', which stands for the character whose CID number in Adobe-Japan1 is xxx.

This extended notation is used in the standard JFM \texttt{jfm-ujis.lua} to typeset halfwidth Hiragana glyphs (CID 516–598) in halfwidth.

11.3 luatexja-adjust

(see Japanese version of this manual)

11.4 luatexja-ruby

This addon package provides functionality of "ruby" (furigana) annotations using callbacks of Lua\TeX-ja. There is no detailed manual of luatexja-ruby.sty in English. (Japanese manual is another PDF file, \texttt{luatexja-ruby.pdf}.)

\textbf{Group-ruby} By default, ruby characters (the second argument of \texttt{ruby}) are attached to base characters (the first argument), as one object. This type of ruby is called \textbf{group-ruby}.

\textsuperscript{11}Useful macros by iNOUE Koich!, for the japanese-otf package.
As the above example, ruby hangover is allowed on the Hiragana before/after its base characters.

**Mono-ruby** To attach ruby characters to each base characters (mono-ruby), one should use `\ruby` multiple times:

```latex
\东西线の\ruby{妙}{みよう}{典}{でん}駅は……
```

**Jukugo-ruby** Vertical bar \(\vert\) denotes a boundary of groups.

```latex
\ruby{妙}{典}{みよう}{でん}駅は……
```

If there are multiple groups in one `\ruby` call, A linebreak between two groups is allowed.

```latex
\vbox{
\hspace{6zw}
\noindent
\ruby{京}{急}{蒲}{田}{けい}{きゆう}{かま}{た}
\kern1zw
\ruby{京}{急}{蒲}{田}{けい}{きゆう}{かま}{た}
\kern5zw
}\parbox{8zw}{uthujxext.sty}
```

If the width of ruby characters are longer than that of base characters, `\ruby` automatically selects the appropriate form among the line-head form, the line-middle form, and the line-end form.

```latex
\vbox{
\hspace{8zw}
\noindent
\ruby{京}{急}{蒲}{田}{けい}{きゆう}{かま}{た}
\null\kern3zw 
\null\kern3zw
\null\kern5zw 
}\parbox{8zw}{uthujxext.sty}
```

11.5 **ltxjext.sty**

p\TeX\ supplies additional macros for vertical writing in the `plext` package. The ltxjext package which we want to describe here is the Lua\TeX\-ja counterpart of the plext package.

**tabular, array, minipage environments**

These environments are extended by `\<dir>`, which specifies the direction, as follows:

```latex
\begin{tabular}<dir>[pos]{table spec} ... \end{tabular}
\begin{array}<dir>[pos]{table spec} ... \end{array}
\begin{minipage}<dir>[pos]{width} ... \end{minipage}
```

This option permits one of the following five values. If none of them is specified, the direction inside the environment is same as that outside the environment.

\begin{itemize}
\item \texttt{y} yoko direction (horizontal writing)
\item \texttt{t} tate direction (vertical writing)
\item \texttt{z} utod direction if direction outside the env. is \texttt{tate}.
\item \texttt{d} dtou direction
\item \texttt{u} utod direction
\end{itemize}

```latex
\parbox<dir>[(pos)]{(width)}{(contents)}
```

\parbox command is also extended by `\<dir>`.\par
This command typeset \( \langle \text{contents} \rangle \) in LR-mode, in \( \langle \text{dir} \rangle \) direction. If \( \langle \text{width} \rangle \) is positive, the width of the box becomes this \( \langle \text{width} \rangle \). In this case, \( \langle \text{contents} \rangle \) will be aligned to left (when \( \langle \text{pos} \rangle \) is 1), center (c), or right (r).

\begin{picture}(x\_size, y\_size)(x\_offset, y\_offset)...
\end{picture}

As described in Subsection 3.3, one can load the luatexja-preset package to use several “presets” of Japanese fonts. This package provides functions in a part of \texttt{japanese-otf} package (changing fonts) and a part of \texttt{PXchfon} package (presets) by Takayuki Yato.

Options which are given in \texttt{\usepackage} but not described in this subsection are simply passed to the \texttt{luatexja-fontspec} \footnote{if \texttt{nfssonly} option is not specified; in this case these options are simply ignored.}. For example, the line 5 in below example is equivalent to lines 1–3.

\begin{verbatim}
\usepackage[no-math]{fontspec}
\usepackage[match]{luatexja-fontspec}
\usepackage[kozuka-pr6n]{luatexja-preset}
\end{verbatim}

\begin{verbatim}
\usepackage[no-math,match,kozuka-pr6n]{luatexja-preset}
\end{verbatim}

11.6 luatexja-preset

As described in Subsection 3.3, one can load the luatexja-preset package to use several “presets” of Japanese fonts. This package provides functions in a part of \texttt{japanese-otf} package (changing fonts) and a part of \texttt{PXchfon} package (presets) by Takayuki Yato.

Options which are given in \texttt{\usepackage} but not described in this subsection are simply passed to the \texttt{luatexja-fontspec}. For example, the line 5 in below example is equivalent to lines 1–3.

\begin{verbatim}
\usepackage[no-math]{fontspec}
\usepackage[match]{luatexja-fontspec}
\usepackage[kozuka-pr6n]{luatexja-preset}
\end{verbatim}

\begin{verbatim}
\usepackage[no-math,match,kozuka-pr6n]{luatexja-preset}
\end{verbatim}

11.6.1 General Options

textspec (enabled by default)

With this option, Japanese fonts are selected using functionality of the \texttt{luatexja-fontspec} package. This means that the fontspec package is automatically loaded by this package.

If you need to pass some options to fontspec, you can load fontspec manually before \texttt{luatexja-preset}:

\begin{verbatim}
\usepackage[no-math]{fontspec}
\usepackage[...]{luatexja-preset}
\end{verbatim}

nfssonly

With this option, selecting Japanese fonts won’t be performed using the functionality of the fontspec package, but only standard NFSS2 (hence without \texttt{\addfontfeatures} etc.). This option is ignored when \texttt{luatexja-fontspec} package is loaded.

When this option is specified, fontspec and \texttt{luatexja-fontspec} are \textit{not} loaded by default. Nevertheless, the packagefontspec can coexist with the option, as the following:

\begin{verbatim}
\usepackage[fontspec]
\usepackage[hiragino-pron,nfssonly]{luatexja-preset}
\end{verbatim}

In this case, one can use \texttt{\setmainfont} etc. to select \textit{alphabetic} fonts.

\begin{verbatim}
\setmainfont\{...\}
\end{verbatim}
match
If this option is specified, usual family-changing commands such as \rmfamily, \textrm, \sffamily, ... also change Japanese font family. This option is passed to luatexja-fontspec, if fontspec option is specified.

nodeluxe (enabled by default)
The negation of deluxe option. Use one-weighted mincho and gothic font families. This means that \mcfamily\bfseries, \gtfamily\bfseries and \gtfamily\mdseries use the same font.

deluxe
Use the mincho family with three weights (light, medium, and bold), the gothic family with three weights (medium, bold, and extra bold), and rounded gothic. Mincho light and gothic extra bold can be by \mcfamily\ltseries and \gtfamily\ebseries, respectively.

• Some presets do not have the light weight of mincho. In this case, we substitute the medium weight for the light weight.
• luatexja-preset does not produce an error (only produces a warning), even if (one of) fonts for \mcfamily\ltseries, \gtfamily\ebseries, \mgfamily do not exist.

expert
Use horizontal/vertical kana alternates, and define a command \rubyfamily to use kana characters designed for ruby.

bold
Substitute bold series of gothic for bold series of mincho. If nodeluxe option is enabled, medium series of gothic is also changed, since we use same font for both series of gothic.

jis90, 90jis
Use JIS X 0208:1990 glyph variants if possible.

jis2004, 2004jis
Use JIS X 0213:2004 glyph variants if possible.

\jfmyoko={(jf.m)}
Use the JFM jfm-(jf.m).lua for horizontal direction, instead of jfm-ujis.1ua (default JFM).

\jfmtate={(jf.m)}
Use the JFM jfm-(jf.m).lua for vertical direction, instead of jfm-ujisv.1ua (default JFM).

jis
Same as jfmyoko=jis.

Note that jis90, 90jis, jis2004 and 2004jis only affect with mincho, gothic (and, possibly rounded gothic) families defined by this package. We didn’t taken account of when more than one options among them are specified.

11.6.2 Presets which support multi weights
Besides bizud, haranoaji, morisawa-pro, and morisawa-pr6n presets, fonts are specified by font name, not by file name. In following tables, starred fonts (e.g. KozGo...Regular) are used for medium series of gothic, if and only if deluxe option is specified.

kozuka-pro Kozuka Pro (Adobe-Japan1-4) fonts.
kozuka-pr6 Kozuka Pr6 (Adobe-Japan1-6) fonts.
kozuka-pr6n Kozuka Pr6N (Adobe-Japan1-6, JIS04-savvy) fonts.

Kozuka Pro/Pr6N fonts are bundled with Adobe’s software, such as Adobe InDesign. There is not rounded gothic family in Kozuka fonts.

\text{\textsuperscript{13}}Provided by \mgfamily and \textmg, because “rounded gothic” is called maru gothic (丸ゴシック) in Japanese.

<td></td>
<td>HG MaruGothic M PRO</td>
<td>HG MaruGothic M PRO</td>
<td>HG MaruGothic M PRO</td>
</tr>
</tbody>
</table>

Note that HG Mincho E, HG Gothic E, HG Soei Kaku Gothic UB, and HG Maru Gothic PRO are internally specified by:

- **default** by font name (HGMinchoE, etc.).
- **jis90, 90jis** by file name (hgrme.ttc, hgrge.ttc, hgrsgu.ttc, hgrsmp.ttf).
- **jis2004, 2004jis** by file name (hgrme04.ttc, hgrge04.ttc, hgrsgu04.ttc, hgrsmp04.ttf).

11.6.5 Define/Use Custom Presets

From version 20170904.0, one can define new presets using \ltjnewpreset, and use them by \ltjapplypreset. These two commands can only be used in the preamble.

\ltjnewpreset\{\textit{name}\}\{\textit{specification}\}

Define new preset \textit{name}. This \textit{name} cannot be same as other presets, options described in Sub-subsection 11.6.1, nor following 11 strings:

- \texttt{mc=mc-l=mc-m=mc-b=mc-bx=gt=gt-m=gt-b=gt-bx=gt-eb=mg-m}

\textit{specification} is a comma-separated list which consists of other presets and/or the following keys:

- \texttt{mc=mc-l=mc-m=mc-b=mc-bx=gt=gt-m=gt-b=gt-bx=gt-eb=mg-m} synonym for mc-b=\texttt{mc-bx=gt-b=gt-bx=gt-eb=mg-m}

- \texttt{mc-b=mc-m=mc-l=mc-bx=gt-eb=mg-m} synonym for mc-b=\texttt{mc-m=mc-l=mc-bx=gt-eb=mg-m}

If \texttt{deluxe} is not specified at loading the package, only \texttt{mc} and \texttt{gt} keys (among above 11 keys) have a meaning.

\ltjnewpreset*\{\textit{name}\}\{\textit{specification}\}

Almost same as \ltjnewpreset. However, if \textit{name} matches a preset which already defined, this command simply overwrite it.
\texttt{\textbackslash ltjapplypreset\{\textit{name}\}}

Set Japanese font families using preset \textit{name}.

Note that \texttt{\textbackslash ltjnewpreset} does not "expand" the definition to define a preset. This means that one can write as the following:

\begin{verbatim}
\texttt{\textbackslash ltjnewpreset\{hoge\}\{piyo,mc-b=HiraMinProN-W6\}}
\texttt{\textbackslash ltjnewpreset\{piyo\}\{mg-m=HiraMaruProN-W4\}}
\texttt{\textbackslash ltjapplypreset\{hoge\}}
\end{verbatim}

\textbf{■Restrictions} Presets which are defined by \texttt{\textbackslash ltjnewpreset} have following restrictions:

- One cannot specify non-embedded fonts (such as Ryumin-Light).
- Some presets, such as \texttt{ipa-hg}, have a feature that fonts are changed according to whether \texttt{90jis} or \texttt{jis2004} is specified. This feature is not usable in presets which are defined by \texttt{\textbackslash ltjnewpreset}.
Part III
Implementations

12 Storing Parameters

12.1 Used dimensions, attributes and whatsit nodes

Here the following is the list of dimensions and attributes which are used in Lua\TeX-ja.

\jQ \text{ (dimension)} \ jQ \text{ is equal to } 1 \ jQ = 0.25 \text{ mm, where "Q" \text{ (also called "級") is a unit used in Japanese phototypesetting. So one should not change the value of this dimension.}}

\jH \text{ (dimension)} \ There is also a unit called "歯" \text{ which equals to 0.25 mm and used in Japanese phototypesetting. This } \jH \text{ is the same } \dimen \text{ register as } \jQ.

\ltj@dimen@zw \text{ (dimension)} \ A temporal register for the "full-width" of current Japanese font. The command } \zw \text{ sets this register to the correct value, and } \text{return} \text{ this register itself.}

\ltj@dimen@zh \text{ (dimension)} \ A temporal register for the "full-height" (usually the sum of height of imaginary body and its depth) of current Japanese font. The command } \zh \text{ sets this register to the correct value, and } \text{return} \text{ this register itself.}

\jfam \text{ (attribute)} \text{ Current number of Japanese font family for math formulas.}

\ltj@curjfnt \text{ (attribute)} \text{ If this attribute is a positive number, it stores the font number of current Japanese font for horizontal direction. If this attribute is negative, it means that the Japanese font for horizontal direction is not loaded—Lua\TeX-ja only knows its size and JFM.}

\ltj@curtfnt \text{ (attribute)} \text{ Similar to } \ltj@curjfnt, \text{ but with current Japanese font for vertical direction.}

\ltj@charclass \text{ (attribute)} \text{ The character class of a JAchar. This attribute is only set on a glyph_node which contains a JAchar.}

\ltj@yablshift \text{ (attribute)} \text{ The amount of shifting the baseline of alphabetic fonts in scaled point (2^{-16} pt).}

\ltj@ykb1shift \text{ (attribute)} \text{ The amount of shifting the baseline of Japanese fonts in scaled point (2^{-16} pt).}

\ltj@tablshift \text{ (attribute)}
\ltj@tkb1shift \text{ (attribute)}

\ltj@autospc \text{ (attribute)} \text{ Whether the auto insertion of } \text{kanjiskip} \text{ is allowed at the node.}

\ltj@autoxspc \text{ (attribute)} \text{ Whether the auto insertion of } \text{xkanjiskip} \text{ is allowed at the node.}

\ltj@icflag \text{ (attribute)} \text{ An attribute for distinguishing "kinds" of a node. One of the following value is assigned to this attribute:}

\text{italic} \ (1) \text{ Kerns from italic correction (/\), or from kerning information of a Japanese font. These kerns are "ignored" in the insertion process of JAglue, unlike explicit } \kern.

\text{packed} \ (2) \text{ Kerns from italic correction (/\), or from kerning information of a Japanese font. These kerns are "ignored" in the insertion process of JAglue, unlike explicit } \kern.

\text{全明星} \ (3) \text{ Penalties inserted for the word-wrapping process (kinsoku shori) of Japanese characters.}

\text{from_ifm} \ (4–67) \text{ Glues/kerns from JFM.}
\text{kanji_skip} \ (68), \text{kanji_skip_ifm} \ (69) \text{ Glues from kanjiskip.}
\text{xkanji_skip} \ (70), \text{xkanji_skip_ifm} \ (71) \text{ Glues from xkanjiskip.}
\text{processed} \ (73) \text{ Nodes which is already processed by ....}
ic\_processed (74) Glues from an italic correction, but already processed in the insertion process of JAglues.

boxbdd (75) Glues/kerns that inserted just the beginning or the ending of an hbox or a paragraph.

\ltj@cat i \ (attribute) Where i is a natural number which is less than 7. These 7 attributes store bit vectors indicating which character block is regarded as a block of JAchars.

\ltj@dir \ (attribute) dir\_node\_auto (128)

dir\_node\_manual (256)

Furthermore, LuaTEX-ja uses several user-defined whatsit nodes for internal processing. All those nodes except direction whatsits store a natural number (hence its type is 100). direction whatsits store a node list, hence its type is 110. Their user\_id (used for distinguish user-defined whatsits) are allocated by luatexbase.newuserwhatsitid.

inhibitglue Nodes for indicating that inhibitglue is specified. The value field of these nodes doesn’t matter.

stack\_marker Nodes for LuaTEX-ja’s stack system (see the next subsection). The value field of these nodes is current group level.

char\_by\_cid Nodes for JAchar which processes by luaotfload won’t be applied, and the character code is stored in the value field. Each node of this type are converted to a glyph\_node after processes by luaotfload. Nodes of this type is used in \CID and \UTF.

replace\_vs Similar to char\_by\_cid whatsits above. These nodes are for ALchar which the callback process of luaotfload won’t be applied.

begin\_par Nodes for indicating beginning of a paragraph. A paragraph which is started by \item in list-like environments has a horizontal box for its label before the actual contents. So ...

direction

These whatsits will be removed during the process of inserting JAglues.

12.2 Stack system of LuaTEX-ja

\textbf{\textit{Background}} LuaTEX-ja has its own stack system, and most parameters of LuaTEX-ja are stored in it. To clarify the reason, imagine the parameter kanjiskip is stored by a skip, and consider the following source:

\begin{verbatim}
\ltjsetparameter{kanjiskip=0pt}ふがふが.%
\setbox0=\hbox{%
\ltjsetparameter{kanjiskip=5pt}ほげほげ}
\box0.ぴよぴよ\par
\end{verbatim}

As described in Subsection 8.1, the only effective value of kanjiskip in an hbox is the latest value, so the value of kanjiskip which applied in the entire hbox should be 5pt. However, by the implementation method of LuaTEX, this “5pt” cannot be known from any callbacks. In the tex/packaging.w, which is a file in the source of LuaTEX, there are the following codes:

```
void package(int c)
{
    scaled h; /* height of box */
    halfword p; /* first node in a box */
    scaled d; /* max depth */
    int grp;
    grp = cur_group;
    d = box\_max\_depth;
    unsave();
```
save_ptr -= 4;
if (cur_list.mode_field == -hmode) {
  cur_box = filtered_hpack(cur_list.head_field,
  cur_list.tail_field, saved.value(1),
  saved.level(1), grp, saved_level(2));
  subtype(cur_box) = HLIST_SUBTYPE_HBOX;

  Notice that unsave() is executed before filtered_hpack(), where hpack_filter callback is executed) here. So "5 pt" in the above source is orphaned at unsave(), and hence it can't be accessed from hpack_filter callback.

Implementation

The code of stack system is based on that in a post of Dev-luatex mailing list

These are two \TeX count registers for maintaining information: \texttt{\ltj@stack} for the stack level, and \texttt{\ltj@group@level} for the \TeX's group level when the last assignment was done. Parameters are stored in one big table named charprop_stack_table, where charprop_stack_table\texttt{[\textit{i}]} stores data of stack level \texttt{i}. If a new stack level is created by \texttt{\ltjsetparameter}, all data of the previous level is copied.

To resolve the problem mentioned in above paragraph "Background", Lua\TeX-ja uses another trick. When the stack level is about to be increased, a whatsis node whose type, subtype and value are 44 (user defined), stack marker and the current group level respectively is appended to the current list (we refer this node by \texttt{stack_flag}). This enables us to know whether assignment is done just inside a hbox. Suppose that the stack level is \texttt{s} and the \TeX's group level is \texttt{t} just after the hbox group, then:

- If there is no \texttt{stack_flag} node in the list of the contents of the hbox, then no assignment was occurred inside the hbox. Hence values of parameters at the end of the hbox are stored in the stack level \texttt{s}.
- If there is a \texttt{stack_flag} node whose value is \texttt{t + 1}, then an assignment was occurred just inside the hbox group. Hence values of parameters at the end of the hbox are stored in the stack level \texttt{s + 1}.
- If there are \texttt{stack_flag} nodes but all of their values are more than \texttt{t + 1}, then an assignment was occurred in the box, but it is done in more internal group. Hence values of parameters at the end of the hbox are stored in the stack level \texttt{s}.

Note that to work this trick correctly, assignments to \texttt{\ltj@stack} and \texttt{\ltj@group@level} have to be local always, regardless the value of \texttt{\globaldefs}. To solve this problem, we use another trick: the assignment \texttt{\directlua{tex.globaldefs=0}} is always local.

12.3 Lua functions of the stack system

In this subsection, we will see how a user use Lua\TeX-ja's stack system to store some data which obeys the grouping of \TeX.

The following function can be used to store data into a stack:

\begin{verbatim}
luatexja.stack.set_stack_table(index, <any> data)
\end{verbatim}

Any values which except nil and NaN are usable as \texttt{index}. However, a user should use only negative integers or strings as \texttt{index}, since natural numbers are used by Lua\TeX-ja itself. Also, whether \texttt{data} is stored locally or globally is determined by \texttt{luatexja.isglobal} (stored globally if and only if \texttt{luatexja.isglobal = 'global'}).

Stored data can be obtained as the return value of

\begin{verbatim}
luatexja.stack.get_stack_table(index, <any> default, <number> level)
\end{verbatim}

where \texttt{level} is the stack level, which is usually the value of \texttt{\ltj@stack}, and \texttt{default} is the default value which will be returned if no values are stored in the stack table whose level is \texttt{level}.

12.4 Extending Parameters

Keys for \texttt{\ltjsetparameter} and \texttt{\ltjgetparameter} can be extended, as in luatexja-adjust.

\footnote{\texttt{[Dev-luatex]} \texttt{tex.currentgrouplevel}, a post at 2008/8/19 by Jonathan Sauer.}
Setting parameters

Figure 11 shows the most outer definition of two commands, \ltjsetparameter and \ltjglobalsetparameter. Most important part is the last \setkeys, which is offered by the \texttt{xkeyval} package.

Hence, to add a key in \ltjsetparameter, one only have to add a key whose prefix is ltj and whose family is japaram, as the following.
\begin{verbatim}
\define@key[ltj]{japaram}{...}{...}
\end{verbatim}

\ltjsetparameter and \ltjglobalsetparameter automatically sets \texttt{luatexja.isglobal}. Its meaning is the following.

\begin{equation}
\text{luatexja.isglobal} = \begin{cases} 
\text{‘global’} & \text{(global assignment)}, \\
\text{‘’} & \text{(local assignment)}. 
\end{cases}
\end{equation}

This is determined not only by command name (\ltjsetparameter or \ltjglobalsetparameter), but also by the value of \texttt{globaldefs}.

Getting parameters

\ltjgetparameter is implemented by a Lua script.

For parameters that do not need additional arguments, one only have to define a function in the table \texttt{luatexja.unary_pars}. For example, with the following function, \ltjgetparameter{hoge} returns a string 42.

\begin{verbatim}
1 function luatexja.unary_pars.hoge (t) 
2 return 42 
3 end 
\end{verbatim}

Here the argument of \texttt{luatexja.unary_pars.hoge} is the stack level of Lua\TeX-ja's stack system (see Subsection 12.2).

On the other hand, for parameters that need an additional argument (this must be an integer), one have to define a function in \texttt{luatexja.binary_pars} first. For example,

\begin{verbatim}
1 function luatexja.binary_pars.fuga (c, t) 
2 return tostring(c) .. ', ' .. tostring(42) 
3 end 
\end{verbatim}

Here the first argument \(t\) is the stack level, as before. The second argument \(c\) is just the second argument of \ltjgetparameter.

For parameters that need an additional argument, one also have to execute the Te\TeX\ code like \ltj@@decl@array@param{fuga} to indicate that "the parameter fuga needs an additional argument".

13 Linebreak after a Japanese Character

13.1 Reference: behavior in p\TeX

In p\TeX, a line break after a Japanese character doesn’t emit a space, since words are not separated by spaces in Japanese writings. However, this feature isn’t fully implemented in Lua\TeX-ja due to the specification of
• We omitted about category codes 9 (ignored), 14 (comment), and 15 (invalid) from the above diagram. We also ignored the input like "^^A" or "^^df".
• When a character whose category code is 0 (escape character) is seen by TeX, the input processor scans a control sequence (scan a c.s.). These paths are not shown in the above diagram. After that, the state is changed to State $S$ (skipping blanks) in most cases, but to State $M$ (middle of line) sometimes.

Figure 12. State transitions of $\text{p}\TeX$’s input processor

callbacks in LuaTeX. To clarify the difference between $\text{p}\TeX$ and LuaTeX, We briefly describe the handling of a line break in $\text{p}\TeX$, in this subsection.

$\text{p}\TeX$’s input processor can be described in terms of a finite state automaton, as that of TeX in Section 2.5 of [1]. The internal states are as follows:

• State $N$: new line
• State $S$: skipping spaces
• State $M$: middle of line
• State $K$: after a Japanese character

The first three states—$N$, $S$, and $M$—are as same as TeX’s input processor. State $K$ is similar to state $M$, and is entered after Japanese characters. The diagram of state transitions are indicated in Figure 12. Note that $\text{p}\TeX$ doesn’t leave state $K$ after “beginning/ending of a group” characters.

13.2 Behavior in LuaTeX-ja

States in the input processor of LuaTeX is the same as that of TeX, and they can’t be customized by any callbacks. Hence, we can only use process_input_buffer and token_filter callbacks for to suppress a space by a line break which is after Japanese characters.

However, token_filter callback cannot be used either, since a character in category code 5 (end-of-line) is converted into a space token in the input processor. So we can use only the process_input_buffer callback. This means that suppressing a space must be done just before an input line is read.

Considering these situations, handling of an end-of-line in LuaTeX-ja are as follows:

A character whose character code is $\text\{ljlineendcomment}$ is appended to an input line, before LuaTeX actually process it, if and only if the following three conditions are satisfied:

1. The category code of $\text{endlinechar}$ is 5 (end-of-line).
2. The category code of $\text\{ljlineendcomment}$ itself is 14 (comment).

\footnote{Its default value is "FFFFF", so U+FFFFF is used. The category code of U+FFFFF is set to 14 (comment) by LuaTeX-ja.}

\footnote{Usually, it is \text{return} (whose character code is 13).}
3. The input line matches the following "regular expression":

\((\text{any char})^*\langle \text{ JAchar} \rangle(\{\text{catcode} = 1\} \cup \{\text{catcode} = 2\})^*\)

**Remark** The following example shows the major difference from the behavior of \TeX.

```latex
\begin{verbatim}
\fontspec[Ligatures=TeX]{Linux Libertine O}
\ltjsetparameter{autoxspacing=false}
\ltjsetparameter{jacharrange={-6}}xあ
y\ltjsetparameter{jacharrange={+6}}zい
u
\end{verbatim}
```

It is not strange that “あ” does not printed in the above output. This is because \TeX \textsc{Gyre Termes} does not contain “あ”, and because “あ” in line 3 is considered as an \textsc{Alchar}.

Note that there is no space before "y" in the output, but there is a space before "u". This follows from following reasons:

- When line 3 is processed by \texttt{process\_input\_buffer} callback, “あ” is considered as an \textsc{JAchar}. Since line 3 ends with an \textsc{JAchar}, the comment character (whose character code is \\texttt{\ltjlineendcomment}) is appended to this line, and hence the linebreak immediately after this line is ignored.

- When line 4 is processed by \texttt{process\_input\_buffer} callback, “い” is considered as an \textsc{Alchar}. Since line 4 ends with an \textsc{Alchar}, the linebreak immediately after this line emits a space.

14 Patch for the listings Package

It is well-known that the listings package outputs weird results for Japanese input. The listings package makes most of letters active and assigns output command for each letter ([2]). But Japanese characters are not included in these activated letters. For \TeX series, there is no method to make Japanese characters active; a patch \texttt{jlisting.sty} ([4]) resolves the problem forcibly.

In Lua\TeX-ja, the problem is resolved by using the \texttt{process\_input\_buffer} callback. The callback function inserts the output command (active character \\texttt{\ltjlineendcomment}) before each letter above \texttt{U+0080}. This method can omits the process to make all Japanese characters active (most of the activated characters are not used in many cases).

If the listings package and Lua\TeX-ja were loaded, then the patch \texttt{lltjp-listings} is loaded automatically at \begin{document}.

14.1 Notes and additional keys

**Variation selectors** \texttt{lltjp-listings} add two keys, namely \texttt{vsraw} and \texttt{vscmd}, which specify how variation selectors are treated in \texttt{lstlisting} or other environments. Note that these additional keys are not usable in the preamble, since \texttt{lltjp-listings} is loaded at \begin{document}.

\texttt{vsraw} is a key which takes a boolean value, and its default value is false.

- If the \texttt{vsraw} key is true, then variation selectors are "combined" with the previous character.

```latex
\begin{verbatim}
\begin{lstlisting}[vsraw=true]
葛城市,葛飾区,葛西
\end{lstlisting}
```

- If the \texttt{vsraw} key is false, then variation selectors are typeset by an appropriate command, which is specified by the \texttt{vscmd} key. The default setting of the \texttt{vscmd} key produces the following.

```latex
\begin{verbatim}
\begin{lstlisting}[vsraw=false,
vscmd=ltjlistingsvstcmd]
葛城市,葛飾区,葛西
\end{lstlisting}
```

57
For example, the following code is the setting of the vscmd key in this document.

```latex
\def\IVSA#1#2#3#4#5{%
  \hbox to1em{\hss\textcolor{blue}{\raisebox{3.5pt}{\normalfont\ttfamily%
    \fboxsep=0.5pt\fbox{\hbox to0.75em{\hss\tiny \oalign{0#1#2\crcr#3#4#5\crcr}}}}\hss}}%
}\}
{\catcode`%=11
  \gdef\IVSB#1{\expandafter\IVSA\directlua{
    local cat_str = luatexbase.catcodetables['string']
    tex.sprint(cat_str, string.format('%X', 0xE00EF+#1))
  })}}
\lstset{vscmd=\IVSB}
```

The default output command of variation selectors is stored in \ltjlistingsvsstdcmd.

- **The doubleletterspace key**  Even the column format is \[c\] fixed, sometimes characters are not vertically aligned. The following example is typeset with basewidth=2em, and you’ll see the leftmost “H” are not vertically aligned.

```latex
\begin{verbatim}
 H :
 H H H H:
\end{verbatim}
```

\texttt{lltjp-listing} adds the doubleletterspace key (not activated by default, for compatibility) to improve the situation, namely doubles inter-character space in each output unit. With this key, the above input now produces better output.

```latex
\begin{verbatim}
 H :
 H H H H:
\end{verbatim}
```

### 14.2 Class of characters

Roughly speaking, the listings package processes input as follows:

1. Collects *letters* and *digits*, which can be used for the name of identifiers.
2. When reading an *other*, outputs the collected character string (with modification, if needed).
3. Collects *others*.
4. When reading a *letter* or a *digit*, outputs the collected character string.
5. Turns back to 1.

By the above process, line breaks inside of an identifier are blocked. A flag \lst@ifletter indicates whether the previous character can be used for the name of identifiers or not.

For Japanese characters, line breaks are permitted on both sides except for brackets, dashes, etc. Hence the patch \texttt{lltjp-listings} introduces a new flag \lst@ifkanji, which indicates whether the previous character is a Japanese character or not. For illustration, we introduce following classes of characters:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td>\lst@ifletter</td>
<td>T</td>
</tr>
<tr>
<td>\lst@ifkanji</td>
<td>F</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Meaning</th>
<th>char in an identifier</th>
<th>other alphabet</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Kanji</th>
<th>Open</th>
<th>Close</th>
</tr>
</thead>
<tbody>
<tr>
<td>\lst@ifletter</td>
<td>T</td>
<td>F</td>
</tr>
<tr>
<td>\lst@ifkanji</td>
<td>T</td>
<td>T</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Meaning</th>
<th>most of Japanese char</th>
<th>opening brackets</th>
<th>closing brackets</th>
</tr>
</thead>
</table>
Note that digits in the listings package can be Letter or Other according to circumstances.

For example, let us consider the case an Open comes after a Letter. Since an Open represents Japanese open brackets, it is preferred to be permitted to insert line break after the Letter. Therefore, the collected character string is output in this case.

The following table summarizes $5 \times 5 = 25$ cases:

<table>
<thead>
<tr>
<th>Prev</th>
<th>Next</th>
<th>Letter</th>
<th>Other</th>
<th>Kanji</th>
<th>Open</th>
<th>Close</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>collects</td>
<td></td>
<td>outputs</td>
<td></td>
<td>collects</td>
</tr>
<tr>
<td></td>
<td></td>
<td>outputs</td>
<td>collects</td>
<td></td>
<td>outputs</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>output</td>
<td>collects</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the above table,

- “outputs” means to output the collected character string (i.e., line breaking is permitted there).
- “collects” means to append the next character to the collected character string (i.e., line breaking is prohibited there).

Characters above or equal to $\text{U+0080}$ except Variation Selectors are classified into above 5 classes by the following rules:

- **ALchars** above or equal to $\text{U+0080}$ are classified as Letter.
- **JAchars** are classified in the order as follows:
  1. Characters whose `prebreakpenalty` is greater than or equal to 0 are classified as Open.
  2. Characters whose `postbreakpenalty` is greater than or equal to 0 are classified as Close.
  3. Characters that don’t satisfy the above two conditions are classified as Kanji.

The width of halfwidth kana ($\text{U+FF61}–\text{U+FF9F}$) is same as the width of **ALchar**; the width of the other **JAchar** is double the width of **ALchar**.

This classification process is executed every time a character appears in the `lstlisting` environment or other environments/commands.

## 15 Cache Management of LuaTeX-ja

LuaTeX-ja creates some cache files to reduce the loading time, in a similar way to the `luaotfload` package:

- Cache files are usually stored in (and loaded from) `$TEXMFVAR/luatexja/`.
- In addition to caches of the text form (the extension is “.lua”), caches of the binary, precompiled form are supported.
  - In loading a cache, the binary cache precedes the text form.
  - When LuaTeX-ja updates a cache `hoge.lua`, its binary version is also updated.

### 15.1 Use of cache

LuaTeX-ja uses the following cache:

**ltj-cid-auto-adobe-japan1.lua**

The font table of a CID-keyed non-embedded Japanese font. This is loaded in every run. It is created from three CMaps, `UniJIS2004-UTF32-{H,V}` and `Adobe-Japan1-UCS2`, and this is why these two CMaps are needed in the first run of LuaTeX-ja.

Similar caches are created as Table 16, if you specified `cid` key in `\jfont` to use other CID-keyed non-embedded fonts for Chinese or Korean, as in Page 26.
Table 16. cid key and corresponding files

<table>
<thead>
<tr>
<th>cid key</th>
<th>name of the cache</th>
<th>used CMaps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adobe-Japan1-*</td>
<td>ltj-cid-auto-adobe-japan1.lua</td>
<td>UniJIS2004-UTF32-* Adobe-Japan1-UCS2</td>
</tr>
<tr>
<td>Adobe-Korea1-*</td>
<td>ltj-cid-auto-adobe-korea1.lua</td>
<td>UniKS-UTF32-* Adobe-Korea1-UCS2</td>
</tr>
<tr>
<td>Adobe-GB1-*</td>
<td>ltj-cid-auto-adobe-gb1.lua</td>
<td>UniGB-UTF32-* Adobe-GB1-UCS2</td>
</tr>
<tr>
<td>Adobe-CNS1-*</td>
<td>ltj-cid-auto-adobe-cns1.lua</td>
<td>UniCNS-UTF32-* Adobe-CNS1-UCS2</td>
</tr>
</tbody>
</table>

ltj-jisx0208.{luc|lub}

The bytecode version of ltj-jisx0208.lua. This is the conversion table between JIS X 0208 and Unicode which is used in Kanji-code conversion commands for compatibility with \TeX.

15.2 Internal

Cache management system of Lua\TeX-ja is stored in \texttt{luatexja.base} (\texttt{ltj-base.lua}). There are three public functions for cache management in \texttt{luatexja.base}, where \texttt{⟨filename⟩} stands for the file name without suffix:

\begin{verbatim}
save_cache(⟨filename⟩, ⟨data⟩)
Save a non-nil table ⟨data⟩ into a cache ⟨filename⟩. Both the text form ⟨filename⟩.lua and its binary version are created or updated.

save_cache_luc(⟨filename⟩, ⟨data⟩[, ⟨serialized_data⟩])
Same as save_cache, except that only the binary cache is updated. The third argument ⟨serialized_data⟩ is not usually given. But if this is given, it is treated as a string representation of ⟨data⟩.

load_cache(⟨filename⟩, ⟨outdate⟩)
Load the cache ⟨filename⟩. ⟨outdate⟩ is a function which takes one argument (the contents of the cache), and its return value is whether the cache is outdated.

load_cache first tries to read the binary cache ⟨filename⟩.{luc|lub}. If its contents is up-to-date, load_cache returns the contents. If the binary cache is not found or its contents is outdated, load_cache tries to read the text form ⟨filename⟩.lua. Hence, the return value of load_cache is non-nil, if and only if the updated cache is found.
\end{verbatim}
